The only anatomic foundation that could help in clearing up the etiology is the proliferation of the villous epithelium in cases of hydatid mole. Even there the differentiation between malignant and benign mole, as claimed by Neumann, could not be maintained. So far we are not able to prognosticate in a case of hydatid mole whether it will be followed by chorio-epithelioma malignum or not.

Marchand explains the proliferation of the lining of the villi in hydatid mole, as caused by the obstructed transit between mother and ovum. This interference with the transportation of nourishment from the maternal blood to the fetus, by means of the epithelial lining of the villi, increases the physiologic energy of proliferation, which is the property of this epithelium. Overnutrition pushes the limit of physiologic proliferation towards the pathologic side. The difference in the time of the expulsion of the fetus determines whether the physiologically deported cells give rise to a mole or to a chorio-epithelioma. Peters accepts this opinion and tries to explain thereby the histogenesis of this growth. According to him it is only the overnutrition which stamps the character of malignancy on these cells which gives them the power to defy the natural protective forces and to build up such a deleterious tumor. In cases of abortion, where the fetus usually has perished some time ago, we might not object to this hypothesis, but not in cases of labor at term and with living child. Peters himself seems to see herein the weak point of his whole theory. In my opinion this theory contains the thought of such energy of proliferation of the trophoblast, that even after differentiation into syncytium and cell layers, it might be able under certain circumstances to acquire a foothold in the maternal organism. The idea of overnutrition itself being able to produce malignancy is against my pathologic feeling. It might very well lead to a hyperplasia and hypertrophy, but not to such an emancipation of the cell that the latter becomes malignant and produces metastases.

THE RELATIONS BETWEEN CYSTIC DEGENERATION OF THE OVARIES AND HYDATID MOLE.

Recently, on account of the frequency of the combination of hydatid mole with cystic changes of the ovaries, some authors have attributed some influence on the degeneration of the villous epithelium and the villi, to the functional activity of these organs. Some years ago Born stated as his belief that the corpus luteum verum of pregnancy is to be considered a gland with internal secretion, whose task is to regulate the process of the imbedding and development of the ovum. Fraenkel has confirmed this theory by numerous animal experiments on rabbits and in this way has proven that the evolution of the ovum depends on the undisturbed function of the corpus luteum. He advanced the hypothesis that through the pressure and tension of the cysts of the diseased ovary, the corpus luteum is damaged in such a way that its normal influence on the ovum can not be exercised and therefore the latter becomes diseased and develops a hydatid mole. Stoeckel later on demonstrated that the multiple cysts of ovaries in hydatid mole, in all cases he was able to examine, were corpus luteum cysts, and that in all these cases lutein cells were to be found spread throughout the stroma of the ovaries. Runge and Pick have corroborated this statement and the latter has named this state "polycystic luteinic degeneration." Relying on the Fraenkel-Born theory of the influence of the lutein secretion, Pick thinks it possible that the overproduction of lutein, as it is to be found in such ovaries, its overabundance might cause a pathologic proliferation of the epithelial lining, with its consequences, the hydatid mole or the chorio-epithelioma malignum. His chief purpose is to emphasize the fact of the frequent presence of lutein cysts and scattered lutein tissue in the ovarian stroma in these cases. He is well aware of the fact that these changes can be seen in other conditions, and that in some cases, as for instance in the one described by me in this paper, the ovaries were of normal size. Whether there were any scattered lutein cells I can not state now, as the sections of the ovaries are not now in my possession.[1] Therefore we can not as yet accept a direct connection, a strict interdependence of these two conditions. What the cause is and the consequence can not be clearly distinguished; the lutein cysts might be the consequence of hydatid mole.

BIOCHEMICAL THEORY OF THE CHORIO-EPITHELIOMA.

The second theory of the etiology of the chorio-epithelioma malignum might, as mentioned above, start from certain changes in the maternal organism. Instead of attributing to the epithelial cell layer an abnormal dignity, as Peters puts it, this theory would assume only the preservation of the physiologic energy of growth, which is owned by all embryonal tissues, until birth.

We have explained above that we regard the detachment of syncytial cells, that is fetal products, as something physiologic, something that takes place in every labor. The question, whether this process occurs during pregnancy, is also discussed and confirmed by Poten's researches. We really do not know any reason why there should not occur such a loosening or deportation of parts of villi, which are immersed in the streaming blood during pregnancy. The epithelial lining of the villi transfers the nourishing material to the fetus. Persistence of these cells during the whole period of pregnancy can hardly be assumed. Its secretions, the products of the fetal metabolism, as well as the dead and living cells, are emptied into the maternal blood. If we attribute to the embryonal cells such a great energy of growth, then the organism of the woman ought to have protective forces against them, forces which annihilate the physiologic deportation of parts of villi. We owe to Ehrlich's ingenious investigations quite a new insight into the biology of the cell. According to his side-chain theory, the animal organism has the power to produce antibodies against foreign cells and their products, so-called cytolysins and heterolysins. Now the organism of the child is not a foreign body in the true sense; it belongs to the same genus. But even in animals of the same genus Ehrlich and Morgenroth, by devising special methods, have succeeded in producing cytolysins, autolysins. These antibodies necessarily have to be formed in the blood of the pregnant woman against the scattered cells and cell products. Veit, Halban, Ascoli have taken up this idea and Veit has called this body syncytiolisin. Obstetrics especially may be expected to derive great benefit from the discovery of isolysins and autolysins. Beside eclampsia, hyperemesis gravidarum, the habitual abortion and some other phenomena, which so long have been ascribed to the mysterious "irritation of pregnancy," will be brought closer to our understanding. The results of these investigations so far still vary greatly. The influence of the serum of the child on the maternal blood is denied by some authors. While Veit has succeeded in establishing the dissolving influence of the syncytiolysins on the human placenta, Ascoli produced albuminuria and eclamptic attacks of isosyncytiolysins. The effect of these antibodies, as Ehrlich states, is not a specific one, that is in syncytiolysins, agglutinating and dissolving for syncytial cells only. They rather display their activity wherever they find fitting receptors. According to Ehrlich's theory, we therefore had to attribute to the body of the pregnant woman the ability to build syncytiolysins, which have to dissolve all possibly scattered embryonal cells. Consequently it is not the wrapping round with fibrin, as Schauta has declared, nor the deficient ability of the blood to coagulate, nor the inability of the blood to secrete fibrin, as Albert suggests, which further or hinder the proliferation of the scattered cells, though these factors might co-operate, but the natural immunity of the maternal body. To attribute to these scattered cells a special dignity, as Peters thinks, is, in my opinion, more hypothetical than our theory of a defect in the normal protective powers of the female system. The latter has rather more probability after the experimental findings, quoted above.

---

[1] The histologic changes in the ovaries of my case, which resemble much more the picture of the so-called carcinoma folliculare of the ovarium, will be described later on.

Whether the deportation took place in earlier months of pregnancy, or only *sub partu*, is, in my opinion, indifferent; the embryonal cells of the villous lining behave like cells of a neoplasm and circulating in the blood, under the most favorable conditions of nutrition have to proliferate, when the protective powers of the body do not take effect.

If we use this theory as a basis for the etiology of the chorio-epithelioma, then the cases of benign metastasis will be explained easily. The scattering is physiologic and the proliferation is naturally facilitated, if a whole villous trunk has entered the circulation. As long as the organism is producing antibodies the deported cell mass will remain local; surrounded by fibrin and blood masses it will be buried or expelled. Local tumors only will be possible in the case of languishing protective powers, as after severe loss of blood, and might be removed by an operation successfully and completely.

A return of the protective forces after general strengthening of the body may hinder the dissemination of the germs. General proliferation is only possible when there is a total lack of immune bodies. The time when the tumor is first manifest and spreads will not so much depend on the mass of disseminated cells as on the ability of the harmed organism to create sufficient receptors to take up the final destroying struggle. After eclampsia, in which the largest quantity of cells are deported, chorio-epithelioma has never, so far as I know, been observed. The development of hydatid mole, too, is more easily understood if we accept this theory. The ovum in the uterus is biologically equal to a parasite, if this comparison may be permitted, and labor only a kind of self-help. The antibodies, formed in the maternal organism, have the property of keeping the trophoblast within bounds. Lack of these will bring on proliferation of the epithelial layer of the villi and in consequence thereof death of the fetus. The same defect explains in the most natural way the frequent appearance of chorio-epithelioma after hydatid mole.

All patients with chorio-epithelioma malignum vaginale after labor at term, in which the uterus has been free from growth, have so far died. During the six years since the publication of Ehrlich's side-chain theory, beside the hemolysins, we have become acquainted with a nephrotoxin, hepatotoxin, neurotoxin, spermatoxin, etc.; and Schmorl, by rendering ineffective the antibodies, produced in the liver of rabbits changes typical for eclampsia, by injection of placental cells. If we can already consider the possibility of destroying carcinoma by cytolysins, how much nearer are we, as I am convinced, to success in fighting the chorio-epithelioma, whose antibodies are no longer far from our understanding, in all those cases where an operation seems to be hopeless? The question is only to restore natural protective forces, which are lost or perhaps only lack points of attachment.

CONCLUSIONS.

1. The syncytium is of fetal origin.
2. The syncytium and the Langhaus-cell are different stages of the same cell, the trophoblast.
3. The chorio-epithelioma malignum is a growth consisting of fetal cells only. As a growth, built up of epithelial cells without blood vessels and connective tissue, it has to be placed in a class by itself.
4. The chorio-epithelioma of the woman is always a consequence of pregnancy; it has nothing to do with teratomas, as these are inborn growths.
5. The chorio-epithelial formations in teratomas of the testicle and the ovary are proving the fetal origin of the syncytium, but are totally different from them. The chorio-epithelial masses in these tumors proceed from the ektodermal cells and are in their histogenesis equal to all other ektodermal products in teratomas, as the neuro-epithelium, etc.
6. The deportation of parts of villi and their epithelial layer is a physiologic fact and probably takes place during the whole period of pregnancy.
7. The epithelial layer of the villus preserves its embryonal energy of proliferation until birth. Therefore a chorio-epithelioma may arise at any time of pregnancy, when the natural protective forces of the maternal organism become deficient.

MESENTERIC EMBOLISM AND THROMBOSIS.

A STUDY OF TWO HUNDRED AND FOURTEEN CASES.

JAMES MARSH JACKSON, M.D.
Out-Patient Physician to the Massachusetts General Hospital.
CHARLES ALLEN PORTER, M.D.
Assistant Surgeon to the Massachusetts General Hospital.
WILLIAM CARTER QUINBY, M.D.
BOSTON.

Though, comparatively speaking, embolism or thrombosis of the mesenteric vessels is rare, it is, nevertheless, one of the most serious of abdominal diseases. This, together with the facts that, until recently, the attention of the profession has not been called to the condition by any comprehensive article, and that those existing are not in the English language; that it forms a disease picture of very difficult clinical diagnosis, and that in any case, operation offers practically the sole chance of recovery, seems to us to justify this investigation.

In the list of cases, 214 in number, on which this article is based, an attempt has been made to collect those cases occurring in our Boston hospitals, and further to collect all those which were accessible from friends in the profession and from the literature. In every case, where possible, the original report has been consulted.

Pathologically, occlusion of mesenteric vessels was described as early as 1847 by Virchow.[1] The clinical picture received but little attention, however, till the article by Litten[2] in 1875.

There followed experiments by several men, notably Cohnheim, Litten, Cohn and others, which showed conclusively that the results of stoppage of blood supply to the intestine are divided into four stages: First, necrosis; second, gangrene; third, hemorrhagic infarction; and fourth, abscess formation.

The general results of stoppage of blood supply are well given by Ribbert in his *Allgemeinen Pathologie* (Leipzig, 1901). He says (p. 162):

> What happens to a vascular area in which the circulation is incompetent? It must necessarily at last be destroyed, but the conditions of this destruction are not always the same.
>
> In the cases in which an end artery is involved the area, under certain conditions, receives so little blood from capillaries or veins, that it becomes essentially paler than the surrounding areas; when beside this, the small amount of blood

---

[2] Virchow's Archiv, vol. lxiii, p. 289.

> which is present loses its color, the area becomes clear, yellow white.
>
> More frequently, however, a marked filling of the area with blood occurs, which, by its presence, stops further accession of blood to the part. Then in the first few hours the area is a red color, but becomes rapidly pale by decolorization of the contained blood, which occurs by separation of the blood coloring matter, this leaving by diffusion or disintegration. Then the area is pale and forms an anemic infarct.
>
> In other cases, either of end artery or of insufficient arterial anastomosis, the afflux of small quantities of blood continues, either from the narrow, arterial anastomoses or from the capillaries or veins. The area then remains red. Microscopically the vessels are turgid, but with no motion of their contents worth mentioning; or often complete stasis occurs. But we soon see something more. We see in the experiment that the blood corpuscles leave the vessels by diapedesis, reaching the surrounding tissues, the spaces of which they fill. Then the area takes on a dark, black-red color, and a firm consistency. A hemorrhagic infarct has occurred, which does not grow pale, but preserves its red color.

He then (p. 166) contrasts intestine to kidney, brain, spleen, etc., in which we usually get an anemic infarct, saying:

> It is different in the case of the intestines. Occlusion of the superior mesenteric artery always causes hemorrhagic infarction. To be sure, there are present anastomoses with other vessels, but these do not suffice for nutrition. But they carry so much blood to the part that the excluded area is made turgid and diapedesis takes place. Then the gut wall and mesentery become black red, and thickened by the mass of blood. Similar hemorrhagic infarction occurs also from venous stasis.

Experiments done by Welch and Mall[3] on this point show, first, that the blood which produces the hemorrhagic infarction enters by the anastomosing arteries, and not by reflux from the veins; second, that the hemorrhage can not be explained by any demonstrable change in the vascular wall, but is the result of retardation and stasis of the circulation, and clumping of red corpuscles in the veins and capillaries, attributable in large part in cases of arterial obstruction to reduction or loss of lateral pulsation of the blood current; third, that the ischemia is increased by the tonic contraction of the intestinal muscles which follows for two or three hours closure of the superior mesenteric artery; and that, fourth, the sudden and complete shutting off of the direct arterial supply to a loop of intestine 5 to 10 cm. in length, is followed by necrosis and hemorrhage of the loop, even when the vessels at each end of the loop are open.

From this it is evident that closure of mesenteric vessels does not, as a rule, call forth the formation of a competent collateral circulation, in spite of their rich anatomic anastomoses, such as is usually established in other areas of the body. The reason for this condition has been the object of much experimental research. (For a critical review of the various theories concerning the absence of collateral circulation, the reader is referred to the recent and very able articles on the subject by Deckart[4] and by Neutra,[5] only the more important of which we abstract here.)

THEORIES CONCERNING ABSENCE OF COLLATERAL CIRCULATION.

Cohnheim[6] explains the intestinal infarction which occurs, in spite of the manifold arcades anastomosing with the vessels of the muscularis, submucosa, and even mucous membrane, by saying that coincident with the closure of a main trunk of an artery, the anastomoses are plugged also, thus forming an artificial end-artery. This, however, by no means explains the process in general, and in only one case (Ponfick[7]) is it expressly stated that a part of an embolus of the main trunk of the superior mesenteric artery became loose and was carried to smaller branches.

Litten's experiments lead him to the conclusion that the superior mesenteric artery is a "functional end-artery."[8] His experiments showed that the formation of a mesenteric collateral circulation needed a higher blood pressure than the blood of the body can reach.

Faber[9] says that the infarction is due to back pressure of blood in the portal system, which overcomes and is greater than the pressure in the anastomosing vessels. The reason why the inferior mesenteric artery does not take up the work of the closed superior artery, he explains by saying that it is a smaller vessel and can not suddenly assume the functions of a larger one. Further, after closure of the superior mesenteric artery, the pressure in the superior mesenteric vein necessarily sinks to *nil* immediately. The pressure in the portal system is thus lowered, making the flow from the inferior mesenteric vein easier. It is thus easier for blood in the inferior mesenteric artery to flow by its natural channel.

Though this view does not cover all the points, it has been accepted by most writers as the best one existing. Rosenbach[10] says:

> An increase of the blood pressure is not necessary for the establishment of a collateral circulation, for normal blood pressure is sufficient, when the resistance in the capillaries forming the collateral circulation is lowered, that is, when there is compensatory dilatation of them. But this can not occur in an intestine which is contracting violently, as is that part which is infarcted. The intestine is thus in the most unfavorable condition. It is contracted ad maximum, thus narrowing the vessels which serve for the formation of anastomoses. It needs by its contractions more blood than usual for its nourishment. Thus a vicious circle is present, and infarct and stasis of marked degree with intestinal hemorrhages occur.

As exceptions to the general rule, a few cases are found in which the postmortem examination showed that a collateral circulation had been formed.

A case of Karcher[11] showed a plugged superior mesenteric artery, but no dilated, collateral anastomoses. The process was at least two months old. Karcher says that the circulation must have been through the colica sinistra. In the case of Chiene[12] we also have evidence of healing. Here both mesenteric arteries were occluded. The circulation was carried out by the superior hemorrhoidal artery, and the colica dextra and sinistra. The retroperitoneal plexus of arteries was much dilated, and served as union between the internal iliac artery and those of the mesentery. In one of Cohn's cases,[13] a previous infarct of a portion of the transverse colon was found, which was healed by collateral circulation. An embolus had lodged in the ramus colica. Collateral circulation was established by the dilated branches of the pancreatico duodenalis and inferior mesenteric arteries, in a case reported by Virchow.[1] Again, the cases of

Kaufmann[14] show what is to be regarded as partially formed collateral circulation. In one case the ileocolic artery was occluded, but that portion of the colon supplied by it was unaffected. In the other case, with the superior mesenteric artery closed, an anastomosis with the pancreatico-duodenalis was found. On this point Neutra[5] says:

> That in just these cases (which out of all the cases are exceptions) collateral circulation could form is explained—besides by the sufficient duration of the process—by an especial condition of the involved vessel system. One can assume that in these individuals the anastomosis between the superior mesenteric artery and the neighboring streams was congenitally richer than the normal. Besides this, one can also assume that in the superior mesenteric artery, before the entrance of sudden occlusion, there was already an impediment of the circulation by some cause (stasis by weak heart, atheroma, emphysema) so that opportunity was offered for a collateral circulation to form, and that then the final embolus did not have its usual severe results.

Of interest here is the case of Robson[15] and that of Roughton.[16] In the first the abdomen was opened for internal hemorrhage, following a wound by a file. The superior mesenteric vein was found bleeding and was tied. In the second, also from trauma, one of the vasa intestini tenuis arteries was ruptured close to its origin from the superior mesenteric artery. It was ligated. In both cases complete recovery resulted.

It is well known that occlusion of mesenteric arteries causes clinical pictures very nearly identical with those following closure of veins, in spite of the differences found from a point of view of pathologic anatomy. It has, therefore, been deemed best by the writers to discuss the cases as a whole, leaving attempts at clinical differentiation for later consideration.

The following twenty-seven cases are new to the literature, and are therefore given in some detail:

CASE 1. (Dr. James Marsh Jackson.)—Man, 65 years. Was always very strong. Served in the Civil War on the coast survey. For twenty years has been resident engineer of a large mine. For several years has had a weak heart, and has been unable to walk upstairs without great discomfort. For a long time has taken laxatives (Carlsbad), more often of late, and in increasing amounts. Now rarely walks more than a block, and even then is obliged to stop for breath. Some years ago had several attacks of angina pectoris. In 1897 had "blood poisoning" of foot from a corn, and was sick for a long time. This was followed by gangrene of the toe and amputation. His family physician has known for several years that patient had diabetes, and what he considered a mitral regurgitation. In January, 1900, the urine contained 7 per cent. of sugar; later only smaller amounts. For past three years has had neuralgia of jaw, for which he has used from 1/20 to 1/10 grain of nitrate of strychnia. Is now taking 1/5 of a grain daily with relief.

Present Illness.—Jan. 4, 1901, patient ate hearty lunch of corned beef, which caused some gastric distress. On the next day the morning movement was constipated. Felt well, however, until January 6, when he ate a breakfast of fish balls and coffee, and had a very small movement following Carlsbad. He had considerable general pain in the abdomen, and lay on the sofa most of the day. Towards night the pain became quite severe, for which he took a large dose of castor oil. The oil operated in about four hours; first movement constipated, next two very loose. After this the pain was slightly relieved, but soon began again and kept him awake most of the night. January 7 the pain still bothered him a great deal, and the abdomen became somewhat distended during the day. January 8, at 1 a. m., the pain became so severe that he could stand it no longer and sent for me.

Physical Examination.—Abdomen distended, especially over the left side; everywhere tympanitic. Very slight general tenderness. Pain constant, dull, with exacerbations all over abdomen, but especially in region of umbilicus. Lungs negative. Systolic murmur at mitral area of heart; aortic second sound not accentuated. Heart otherwise negative. No pyrexia; pulse slightly intermittent. A high enema repeated in an hour had no result. Morphia was then given and he slept through the rest of the night.

January 8, 8 a. m. The enema was repeated without any result. Castor oil was then given, but did not operate. In the evening Dr. F. C. Shattuck saw him in consultation and concurred in the diagnosis of intestinal obstruction of unknown cause; operation not advised. Repeated doses of Seidlitz powders were then given. No movement followed; no gas. At night ¼ gr. morphia was again given. At this time there was moderate distension of the abdomen; general tympanites; no tenderness on pressure. Pain was general over the abdomen, especially marked at the umbilicus. Patient restless, preferring to sit up most of the time. Desires to pass gas but can not.

January 9. Bowels have not moved during the past night. The abdomen is more distended; the pulse is rather poor, and the patient looks rather seedy. Showed considerable improvement after 1/5 gr. of strychnia. In consultation with Dr. J. Collins Warren the condition above described was found. Rectal examination showed a mass the size of a small orange, high up toward the middle line, which felt like an impacted omega loop. No fecal matter in the rectum. A high enema of oil was then given, followed by one of magnesium sulphate, glycerin and water. Three hours later a movement took place, consisting of about two quarts of fecal matter; no blood or mucus. More comfortable after this. Pulse regular and of good volume, but still intermits occasionally. White count: 13,400. Temperature 100, pulse 108, respiration 25. Some thirst.

January 10. Fairly good night. Abdomen still distended. Some belching of gas, no vomiting. Oil and magnesium enemata repeated with two good results. Has taken nourishment every two hours in small amounts. Rather restless all day, complaining of general discomfort in abdomen. At night abdomen seemed harder in right iliac region, and very tympanitic over left iliac and epigastric regions. Color good; respiration rather rapid, but not labored. Slight nausea, but no vomiting. Very thirsty. Has passed no gas and has not much pain. Bowels have moved four times during the day.

January 11. Slept only a short time last night, when he became very restless and complained of considerable pain in epigastrium. Drank freely of water and liquid nourishment. At 3:30 a. m. had a severe pain in epigastrium. Morphia had but little effect. Pulse fairly good. At 7:30 a. m. considerable pain, bad pulse, slightly cyanotic, respiration gasping. He responded well to 1/5 gr. of nitroglycerin, and at 9:30 a. m. was quite comfortable. Operation was considered, but given up on account of condition of the patient. At noon he again collapsed and large doses of stimulants were necessary to obtain any reaction. From this time on he gradually failed and died at 3 p. m. Before death he had an involuntary movement and passed gas. After death about two quarts of dark brown fluid, smelling of stomach contents, flowed from mouth and nose. The stomach had evidently not passed anything along for hours.

Analysis of Urine.—Dr. J. Bergen Ogden, Harvard Medical School. Jan. 11, 1901. Urine in 24 hours small, specific gravity 1033½, color high, amount of sediment considerable, reaction strongly acid, chlorids much diminished, urophæin increased, E. phosphates much diminished, indoxyl much increased, alk. phosphates diminished, urea 1.84 per cent., uric acid increased, albumin very slight trace. Sugar present, 3.57 per cent. No acetone or diacetic acid. Bile pigments absent. Sediment, numerous granular and brown granular casts, some with renal cells, abnormal blood and little fat adherent. Numerous free renal cells, and a few blood globules.

---

[14] Virchow's Archiv, vol. cxvi, p. 353.
[15] British Med. Jour., 1897.
[16] Lancet, 1899.

A few small caudate cells as from renal pelvis. We find this urine to contain sugar. The normal solids are all diminished excepting the uric acid. The indoxyl is very high, which is confirmatory of the diagnosis of intestinal obstruction. The chlorids, phosphates and urea are diminished, probably on account of a low diet. The very low chlorids might also be consistent with a serous effusion. There is considerable disturbance of the kidneys, apparently of the nature of an active hyperemia, rather severe and probably due to a toxemia. There is also evidence of an irritation of the pelvis of the kidney, probably from the same cause. As to the meaning of the sugar, there may have been a diabetes mellitus antedating the present trouble. On the other hand, the sugar may be secondary to the marked abdominal trouble. In the absence of previous history pointing to diabetes, the glycosuria should be considered secondary.

AUTOPSY. DR. W. F. WHITNEY, HARVARD MEDICAL SCHOOL.

Jan. 12, 1901, 18 hours postmortem. The body of a large man with abundant fatty tissue. Rigor mortis present. The body was slightly warm with marked lividity of the dependent portions.

Head.—Not opened.

Pericardium.—Contained a normal amount of fluid.

Heart.—Large. Weighed 400 grams. The valves were normal in appearance. The mitral valve measured 11 cm., and the tricuspid 13 cm. The aorta showed numerous opaque, yellow and calcified patches on its inner surface. The openings of the coronaries were slightly obstructed, and there was a similar condition to that found in the aorta, but less extensive throughout these arteries. The heart substance was pale.

Microscopic Examination.—A slight increase of the fibrous tissue was found between the bundles of muscular fibers, which were somewhat atrophied, otherwise there was nothing remarkable.

Lungs.—Somewhat adherent to the chest cavity and rather engorged in blood in the dependent portions, but otherwise not remarkable.

Abdominal Cavity.—Contained a moderate amount of bloody, serous fluid. The coils of the intestines were very much distended with gas and of a dark, bluish-red color. The stomach itself was normal. The ileum, for the greater part of its course, was discolored, bluish-red in color, the membrane injected with a little bloody mucus in the interior, and about midway in this part the walls were thickened through infiltration of blood. On section the veins leading to this point were found filled with a dark red, loosely adherent antemortem thrombus. The lower two feet of the ileum and the head of the colon were normal. The greater part of the ascending and transverse colon presented a similar aspect to that of the ileum but less in extent. The veins leading to this were also found to be thrombosed in a like manner.

Pancreas.—It was imbedded in fatty tissue, but appeared normal to the eye.

Liver.—Was of normal size. On section it was rather opaque and yellow with indistinct lobular markings. Microscopic examination showed atrophy of the liver columns, slight increase of the fibrous tissue and fatty infiltration of the cells.

Spleen.—Small and soft.

Kidneys.—One of them weighed 200 grams. On section the surface was somewhat pale, slightly opaque with marked injection at the base of the pyramids.

Microscopic Examination.—The vessels of the malpighian bodies were found to be dilated and the connective tissue between the tubules was increased, with a marked atrophy and granular degeneration of the epithelium. The arteries of the kidney were considerably thickened, but this was in general diffuse. In the straight tubules were a few hyaline casts. The thrombosed vessels in the mesentery showed very little change in the wall of the vein that would be regarded as a cause for the thrombosis. In one of the pieces examined, in addition to the vein, a small artery was also found to be thrombosed, the wall of which showed a marked thickening and irregularity of the intima, and to which a thrombosis was very intimately adherent, and seemed as if it might have been the starting point of the process.

Diagnosis.—Arteriosclerosis with hypertrophy of the heart; slight, chronic interstitial myocarditis; hepatitis and nephritis; thrombosis of the mesenteric vein and artery; infarction of the intestine; commencing gangrene.

It is to be regretted that the pancreas was not examined microscopically in this case, and that a thorough dissection of the mesenteric vessels could not have been made. It is, however, fair to assume that the thrombosis could not have extended further than the secondary branches, otherwise the entire intestinal tract would have been infarcted, which is shown above was not the case. It is probable that the thrombosis was due to mechanical pressure of the overloaded colon on vessels in which the circulation was deficient from conditions of the walls of the vessels and the heart.

CASE 2 (Dr. Gannett).—A. R., woman, 65 years, entered Massachusetts General Hospital May 18, 1902.

Family History.—One sister has myxedema, one brother and sister died of tuberculosis.

Past History.—Scarlet fever and measles as child. For eight to ten years has been treated for heart trouble.

Present Illness.—Has been failing gradually for four to five years, and is troubled with dyspnea and palpitation. Has had several severe attacks of orthopnea in last few years. Her present attack has lasted six to eight months, but she did not stay in bed all the time. At times has attacks of severe precordial pain, bearing no relation to exertion. For one or two months legs have been swollen, the swelling gradually increasing and extending upward. No swelling of face and hands. Appetite fair. Vomits occasionally, but only after coughing. Bowels regular. Temperature 98.6, pulse 80, respiration 40.

Physical Examination.—Well developed and nourished. Complains of precordial distress. Cheyne-Stokes respiration. Lungs, râles at both bases, otherwise negative. Heart, apex, fifth space six and one-half inches from middle line. Enlarged, sounds distant and feeble. Systolic murmur at apex. At third left interspace a long, loud diastolic murmur. Pulmonary second sound increased. Pulse regular, small volume, rather high tension, arterial walls thickened. Abdomen large, lax, much subcutaneous fat, with marked dullness on percussion, extending well up into flank, dullness shifting with change of position. No tenderness, nothing abnormal felt. Very marked edema of thighs, legs and feet. Reflexes normal. Blood, hemoglobin 90 per cent., whites 13,000. Urine, high color, acid 1,023. Albumin, slightest possible trace; sugar absent, chlorids diminished, urea 2.77 per cent.; sediment shows very rare hyaline cast and abnormal blood globule; considerable blood, and some squamous cells; many bacteria.

Clinical Diagnosis.—Hypertrophy and dilatation of heart, arteriosclerosis, failure of compensation.

May 21. Considerable improvement in pulse since entrance, but has much distress at times with breathing. Is very noisy.

May 23. Pulse and general condition remain about the same. Still considerable dyspnea, but not so marked as at entrance. Incontinence of urine and feces. Edema of legs and abdomen is increasing.

May 25. Considerable hematemesis is present.

May 26. General condition not so good. Râles more numerous. During afternoon became unconscious, and failed rapidly. Died 6:15 p. m. Temperature never went above normal, pulse gradually increased to 110.

AUTOPSY. DR. J. H. WRIGHT.

Arteriosclerosis with slight dilatation of aorta. Hypertrophy and dilatation of heart. Thrombus in right auricular appendix of heart. Embolic thrombus of branches of pulmonary artery in each lung, with hemorrhagic infarcts of lungs. Stenosis of celiac axis, and superior mesenteric artery at their origin. Obturating thrombus of the superior mesenteric artery. Chronic, passive congestion of lungs, spleen, liver and intestines. Double hydrothorax. Anasarca. Senile degeneration of kidneys and uterus. Chronic perisalpingitis and perioöphoritis. Adenoma of left adrenal. Chronic perisplenitis. Obsolete tuberculosis of pleura. Right otitis media, umbilical hernia. Cholelithiasis. A very few cc. of fluid in pelvic cavity. A small piece of omentum adherent to the abdominal wall, in the region of the umbilicus. Anterior margin of right lobe of liver, two fingers' breadth below costal margin in mammillary line. The mucosa of small intestine shows injection of small vessels, and in places the valvulæ conniventes are of a dark red, hemorrhagic appearance. No ulcers. Abdominal cavity and intestines otherwise negative.

Case 3 (Dr. J. J. Minot).—E. H., widow, 68 years, entered Long Island Hospital, Nov. 10, 1903.

Previous History.—General weakness, with nausea and vomiting.

Physical Examination.—Well developed, slightly emaciated. Somewhat weak, answers slowly but rationally. Anemic. Left pupil slightly larger than right, reaction normal. Tongue is protruded, straight, somewhat dry and coated. Pulse irregular, slightly rapid, of fair volume and tension. Arteries excessively calcified. Chest expansion fair. Heart sounds weak, no murmurs heard. Lungs, good resonance throughout, moist râles in both lower backs. Abdomen, lax and tympanitic, no tenderness or tumors. Liver and spleen normal, not palpated. Extremities, knee-jerks and plantars present. Patient is able to move left leg and arm but slightly, and with less strength than on right.

Clinical Diagnosis.—Myocarditis, arteriosclerosis, interstitial nephritis, rheumatoid arthritis.

Nov. 11, 1903. Patient slept well during the night, and this morning was comfortable. About five minutes after she had been talking with the nurse in her usual manner, she suddenly became pulseless and white, and vomited a large amount of thin, dark fluid, filled with dark, membranous material, varying from small fragments to 2 cm. in diameter. Artificial respiration was of no avail, and patient died.

Examination of urine, specific gravity, 1,023 acid, very slight trace of albumin, sugar absent, bile absent. Several squamous cells, occasional hyaline and granular casts.

Examination of vomitus. Dark brown liquid. Lactic acid and blood present.

AUTOPSY. DR. G. B. MAGRATH.

Anatomic Diagnosis.—Chronic adhesive pleuritis, chronic adhesive pericarditis, hypertrophy and dilatation of heart, emphysema of lungs, fatty metamorphosis of liver, chronic nephritis, multiple infarcts of ileum, senile endometritis, mural thrombus of aorta, general arteriosclerosis, edema of brain, acute fibrinous pericarditis, double hallux valgus. Several coils of the lower part of the ileum are united to one another by fresh, fibrinous adhesions. The coils at the site of the adhesions injected, dark red, and marked by opaque, white patches. The mesentery at the site of these areas is thickened, on section, edematous, the cut surface yielding on pressure, in addition, puriform fluid. These coils lie in the pelvis. Vermiform appendix, and mesenteric lymph nodes normal. On section, the above coils show considerable loss of substance, involving the mucous membrane, the area extending completely around the intestine. Color, opaque, yellowish brown. In places, partly detached sloughs are present, about 2 cm. in width; 30 cm. of gut are involved in lower one-third of ileum.

Aorta on section shows some general dilatation; circumference at the left subclavian, 7.5 cm.; the inner surface is marked by numerous indentations, alternating with elevations, the former calcareous and shell-like, the latter white, or yellowish white; 7 cm. above the celiac axis the front wall shows two regions, approximately 1 cm. in diameter, overlaid with adherent, gray-red clots. One of these clots is somewhat sessile: the lower part of the abdominal aorta and the common iliac are almost wholly calcified.

Microscopic examination shows arteries of involved gut occluded by arteriosclerotic thickening, with few thrombi in finest branches.

Case 4 (Dr. R. H. Fitz).—B. J., 54 years, widow, cigar maker. Entered Massachusetts General Hospital, Jan. 24, 1903.

Previous History.—Pleurisy three years ago, no other illness. Has had 11 children, youngest 15 years ago; one miscarriage before last child was born. Menopause 4 years ago. Tea, two cups per day. Seldom takes alcoholic liquor.

Present Illness.—Two weeks ago, while in bed in the morning, patient was awakened by pain in the right hypochondrium, of considerable severity, dull and heavy in character, not radiating. A few minutes later she vomited, and continued to vomit all the forenoon, with gradually diminishing frequency. Vomitus was slight in amount, green and bitter. There was no chill or feverishness. Pain could not be traced to anything unusual in diet. Bowels had been regular. After this attack, patient felt well until six days later, when a second attack of pain and vomiting occurred. This time the pain did not disappear, but has continued with greater or less severity up to the present time (kept her awake all last night, but is better to-day.) Has vomited almost every day this week (to-day at least 10 times). Has been able to retain but very little nourishment. She has felt cold most of the time, but has noticed no feverishness. Has noticed no jaundice. Bowels have only moved twice in last week, nothing abnormal noticed in character of stools. Urine is red and "thick" and burns as she passes it. Sleep has been poor on account of pain. No appetite.

Physical Examination.—Well developed, somewhat obese. Skin and mucous membrane of good color. Pupils equal and react. Teeth, upper false, many lower ones wanting. Tongue moist, with slight white coat. Throat negative, lungs negative. Heart, apex palpable, fifth space, 4¼ inches from median line. Right border dullness 1¾ inches to right of median line. Sounds very irregular in force and rhythm. Pulmonic second sound slightly increased. No murmurs. Pulse very irregular, rather small volume, and low tension. Abdomen, large, flabby, tympanitic. In the right lower quadrant there is marked tenderness and resistance to palpation, most marked midway between umbilicus and anterior superior spine of right ilium. In the lower abdomen is felt a mass, tender on palpation, and elongated in transverse diameter. No tenderness or spasm in region of gall bladder. Liver dullness from sixth rib to one inch above costal margin, edge not felt. Spleen negative. Reflexes normal. Slight edema of ankles. Temperature 102, pulse 90, respiration 25.

Diagnosis.—Acute endocarditis.

January 24. Blood, hemoglobin 90 per cent., whites 20,200.

January 25. Urine high color, acid 1,030; albumin, large trace; no sugar, no bile, no diazo. Chlorids diminished, urea 3.03 per cent. Sediment, few hyaline casts, with renal cells, and oil globules adherent, many fine and coarse granular casts, some with renal cells adherent. Rare compound granule cell. Numerous squamous epithelial cells. Few leucocytes and small round cells. No blood seen.

January 26. Whites 28,400. Marked iodophilia.

January 27. Patient has grown steadily worse since entrance. Temperature increased and rising, and pulse steadily rising. Complained of abdominal pain, but for the last twenty-four hours has been semi-conscious. Abdomen, though soft, is generally tender. Cheyne-Stokes respiration. Heart action very irregular in force and rhythm. Died, 6:35 on January 27.

AUTOPSY. DR. J. H. WRIGHT.

Anatomic Diagnosis.—Fibrous endocarditis of mitral valve (mitral stenosis). Fibrous endocarditis of aortic and tricuspid valves. Hypertrophy and dilatation of the heart. Thrombi in the left auricular appendix. Embolism and thrombosis of branches of the superior mesenteric artery, with hemorrhagic infarction of the cecum and portions of the ileum and ascending colon. Infarcts in the spleen and kidneys. Thrombosis of a large branch of the superior mesenteric vein. Meckel's diverticulum. Cholelithiasis. General peritonitis.

Icterus, especially of anterior portions of trunk. Head not examined. Small amount of opaque fluid in peritoneal cavity, with grayish yellow flocculi. The coils of the intestine generally show marked injection of the serosa, and at their margins of contact present grayish yellow streaks of fibrinous exudate.

Cover-glass specimen from this exudate shows many leucocytes, and innumerable bacteria, among which are bacilli and micrococci. The walls of the cecum and one-half the adjoining ascending colon, and over a distance of 100 cm. of ileum, show marked changes in color. In the situation of the portion of the ascending colon mentioned, the cecum and lower part of the ileum are black to black-red in color and gangrenous in appearance. Higher up the color fades out gradually from the blacker, gangrenous appearing condition of the lower portion, to the normal appearing intestine, about 100 cm. from the ileocecal valve. The change in color varies from the black-red of the lower portion to gray-red, and beyond the distance mentioned to the normal color. The parietal and visceral peritoneum present more or less of a grayish fibrinous exudate in places. Lungs, no adhesions, negative. Pericardium negative. Heart, old endocarditis of mitral aortic and tricuspid valves. Aorta, negative.

Superior mesenteric artery: At point where ileocolic branch is given off, is an occluding, gray-red, fleshy mass, which is slightly adherent at one point to the intima. This mass is continued into the ileocolic branch, and its branches as gray-red to blackish-red masses, and on following out two or three of the larger branches of the ileocolic it is seen to be continuous in them, till they disappear in the gangrenous portions of the ileum and cecum. In a large radicle of the superior mesenteric vein of the portal system, which arises from the region of the cecum and the ileum, there is, in its lumen, over a distance of several centimeters, a gray-red thrombus-like mass occluding it. This material is invested by a grayish-red, membranous-like covering, and on section shows rather blackish-red, slightly soft central portions, with somewhat denser, gray-red peripheral portion. Liver, negative. Gall bladder, spleen, kidney, etc., as above. No ulcerations in intestines on section, and except for gangrenous portions already described, they are not remarkable. Appendix negative.

There is given off in the ileum, at a point about 90 cm. from the ileocecal valve, a diverticulum 5 cm. long by 2 to 3 cm. wide, the lumen and mucosa of which are continuous with those of the intestines.

Case 5 (Dr. Fitz).—J. K., man, 25 years, entered the Massachusetts General Hospital Dec. 16, 1898.

Clinical Diagnosis.—Gastric ulcer. Secondary anemia. Hematemesis and melena. Picture that of cirrhosis with ascites. Gradual loss of strength, and death with subnormal temperature.

AUTOPSY.

Thrombosis of portal, superior mesenteric, and splenic veins, and of some of the radicles. General anemia. Superficial ulceration in mucosa of stomach. Perisplenitis. Hyperplasia of spleen. Old pleural adhesions. Fatty degeneration of heart. Edema piæ. Peritoneal cavity, slight amount clear fluid. Intestines smooth, shiny and pale. Heart not remarkable. Liver small. In portal vein, pink, firm, fleshy mass, adherent to wall, which extends up to where the vein breaks into liver branches. The thrombus divides and extends slightly into the liver. At origin of portal vein the thrombus divides and extends along the splenic and superior mesenteric vein. In this latter the thrombus can be easily traced down into some of the finer radicles in the mesenteric insertion of the intestine. The character of the thrombi change in the smaller vessels to a gray-red, firm, fibrinous material, adherent to the wall, with intervals of a darker red, soft blood clot material. The splenic vein presents a similar condition to the superior mesenteric, near the end of the superior mesenteric vein, a calcareous plate, size of finger nail. Intestines show some reddening of mucosa. Stomach on section, horse-shoe shaped, superficial loss of substance near pylorus.

The following four cases are from the Johns Hopkins Hospital, Baltimore, and are published by the courtesy of Dr. J. C. Bloodgood:

Case 6 (reported by Dr. Bloodgood). C. C., male, age 52, engineer.

Past History.—Had been a soldier.

Present Illness.—Three weeks ago sudden abdominal pain, not very severe in character, associated with vomiting. Since then intervals of moderately severe pain, chiefly in umbilical region, and vomiting. A few days before admission, acute abdominal pain in region of umbilicus, with vomiting. This attack was aggravated by the administration of cathartics on the next day. No passage of fecal matter, blood or flatus, from this time, three days before admission. Nothing retained by stomach. Abdomen slightly tender above and to right of umbilicus and moderately distended. On admission to the surgical wards at Johns Hopkins Hospital, Sept. 15, 1896, examination showed patient to be excessively fat. Temperature 100 degrees, pulse 72, respiration 24. Facies typical of a severe, intraperitoneal lesion. Abdomen moderately distended, slight muscle spasm, but no tenderness. Palpation difficult, on account of thick abdominal walls. No mass detected on palpation. Rectal examination negative, no fecal matter in rectum. Prepared for operation at once.

OPERATION.

Laparotomy September 15, by Dr. Bloodgood. Under ether anesthesia, a large moveable mass was felt slightly to right and above umbilicus. Bloody fluid in peritoneal cavity, no fecal odor. The moveable mass proved to be omentum adherent to coils of small intestine beneath it. The mass was excised. About 8 cm. of a loop of ileum was gangrenous; the neighboring intestine was congested and covered with fibrin. No perforation. No fecal extravasation. The mesentery seemed normal. The omentum and mesentery very large from fatty deposit; intestine not greatly distended. The gangrenous loop of intestine was drawn out of the wound, and the intestine grained by tubes, inserted above and below. The operation lasted one hour, transfusion of salt solution (1 liter) at end.

After operation patient vomited a great deal of bile-stained fluid. This vomiting continued intermittently during the next three days.

September 17. Gangrenous intestinal loop came away from wound, without bleeding. Temperature 100.5. Pulse, 120. Pulse became very weak during night and rose to 160.

September 18. Temperature 103. Death 10:30 a. m.

AUTOPSY SEPTEMBER 18. DR. FLEXNER.

Anatomic Diagnosis.—Thrombosis of mesenteric veins, necrosis and gangrene of small intestine, general fibrino-purulent peritonitis. Abscess in omentum. Operation wound. Extension of venous thrombosis in portal vein. Congestion of liver and spleen. Chronic, diffuse peritonitis. Chronic interstitial orchitis. Hydrocele. The jejunal loops within the abdominal cavity were much dilated, dark in color, and contained much fluid. The ileal loops were much less distended, the large intestine moderately distended. The gangrenous loops involve the lower end of the jejunum, and the beginning of the ileum. The jejunum adjoining the gangrenous portion very dark in color. The superior mesenteric artery was free. The superior mesenteric vein and its branches to the gangrenous loop and to the intestine on either side were occluded by firm, partially adherent thrombi. The main trunk of the portal vein was also filled by firm thrombi extending from that in the mesenteric vein.

Case 7 (reported by Dr. Mitchell).—G. W., male, age 41, saloonkeeper. Patient was admitted to the Johns Hopkins Hospital as an emergency case July 18, 1900. Had been suffering severely for four days with agonizing pain just to the left of the umbilicus. Considerable nausea and vomiting for last 36 hours. No movement of bowels for two days before admission.

On admission, condition very alarming. Temperature 102 degrees, pulse 140, fair volume. Respiration 31 to minute, thoracic. Skin bathed in perspiration. Lips and mucous membranes pale. Abdomen uniformly distended, tender on pressure, especially on right side. Liver dullness obliterated in upper line. Left side of abdomen tympanitic on percussion, dullness over right lower abdomen, extending nearly to median line. Palpation not possible because of tenderness. Below umbilicus there was a prominence visible in the median line. No visible peristalsis. The general aspect of the man strongly suggested a severe internal hemorrhage. Dr. Mitchell made

Cover-glass specimen from this exudate shows many leucocytes, and innumerable bacteria, among which are bacilli and micrococci. The walls of the cecum and one-half the adjoining ascending colon, and over a distance of 100 cm. of ileum, show marked changes in color. Case 7 (reported by Dr. Mitchell).—G. W., male, age 41, saloonkeeper. Patient was admitted to the Johns Hopkins Hospital as an emergency case July 18, 1900. Had been suffering severely for four days with agonizing pain just to the left of the umbilicus. Considerable nausea and vomiting for last 36 hours. No movement of bowels for two days before admission.

On admission, condition very alarming. Temperature 102 degrees, pulse 140, fair volume. Respiration 31 to minute, thoracic. Skin bathed in perspiration. Lips and mucous membranes pale. Abdomen uniformly distended, tender on pressure, especially on right side. Liver dullness obliterated in upper line. Left side of abdomen tympanitic on percussion, dullness over right lower abdomen, extending nearly to median line. Palpation not possible because of tenderness. Below umbilicus there was a prominence visible in the median line. No visible peristalsis. The general aspect of the man strongly suggested a severe internal hemorrhage. Dr. Mitchell made introducing the light into the viscus have been added in order to make this method easier.

The field of view in these instruments is a very small one on account of the absence of a lens system, so that locating the ureteral openings usually requires a long search. All assertions to the contrary lead more to doubting the reliability of the reports than to change the expressed opinion which is based on a thorough trial of these instruments and on numerous observations of the work of others. The same holds good in regard to the Pawlik-Kelly method in females. This method lost its right to existence since instruments are placed at the command of the profession that allow of a far superior examination without placing the patient in a disagreeable position, without necessitating dilation of the urethra and without exposing the patient to the dangers of general or local anesthesia.

Having excluded the above discussed group of instruments it remains to consider the features and possibilities of the other cystoscopes which are all built on the two principles laid down by Nitze: introduction of the source of light into the viscus, and the enlarging of the field of view by an appropriate lens system. Experience has proven that the most satisfactory results in cystoscopy are always achieved by dilating the bladder with sterile water or another transparent sterile fluid. Casper recommends 1 to 5,000 solution of oxycyanate of mercury.

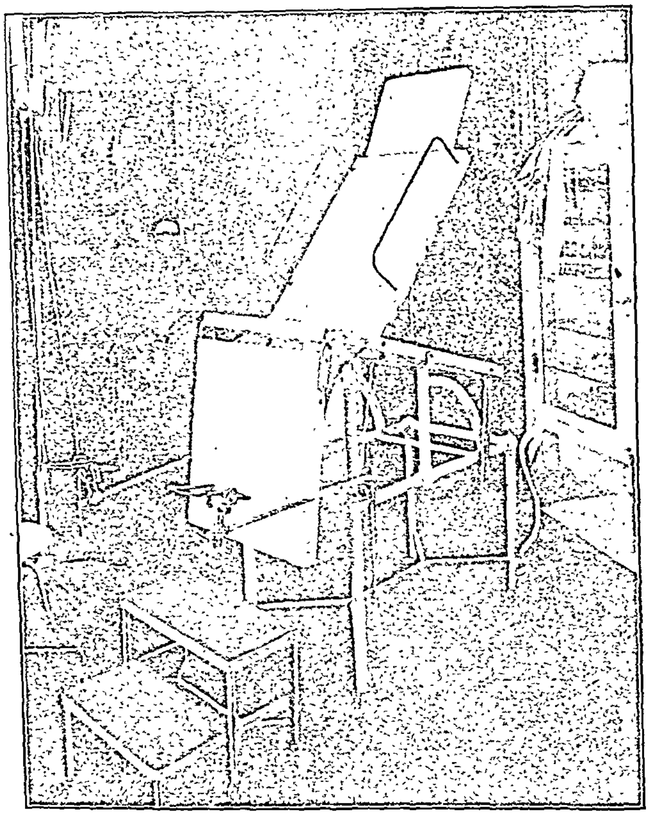

Fig. 1.—Chair for cystoscopy.

Catheters and cystoscopes are lubricated with pure glycerin or any sterile lubricant that readily dissolves in water, so that the lamp and the window are rapidly cleared after insertion. Casper recommends the following composition for lubrication:

℞.	Hg. oxycyanati		246
	Glycerini puri	20	
	Tragacanthi	3	
	Aquæ destil. sterilis	100	

In the case of an infected bladder the viscus is first flushed with a non-irritating silver solution, and this same procedure is repeated after the completion of the examination by the cystoscope.

Before withdrawing the ureteral catheters a few drops of a non-irritating silver solution (such as 1 to 1000 protargol or 1 to 500 argyrol solution) are instillated into the ureters.

The bladder is to be filled as full as possible with the sterile water or other transparent fluid, without causing the patient pronounced discomfort. There is no set quantity suitable for all cases. Thus we smooth, as much as possible, all folds and recesses and flatten out the trigonum; then we gain sufficient space for free movements and manipulations of the cystoscopic beak, although a certain loss of water by dribbling through the conducting canal is unavoidable during the inserting of the catheters, change of tubes and so on.

A very important feature of the whole procedure is the posture and position of the patient. Although it is possible for the very experienced examiner to catheterize a ureter in almost any position, one should always endeavor to succeed in a position which is least disconcerting to the patient and most advantageous for the operator. We prefer having the patient in a sitting posture on a chair which is high enough to permit free manipulations without forcing the operator into a crouching position, which soon becomes tiresome and interferes with steady work. The seat of the chair is slightly elevated, so that the pelvis of the patient is somewhat raised. It is very important not to have the hip joints too forcibly flexed. It is apparent that if the knees are forced above the seat that the inclination of the pelvis disappears entirely and consequently the trigonum will be brought in an unfavorable angle for inspection (Fig. 1).

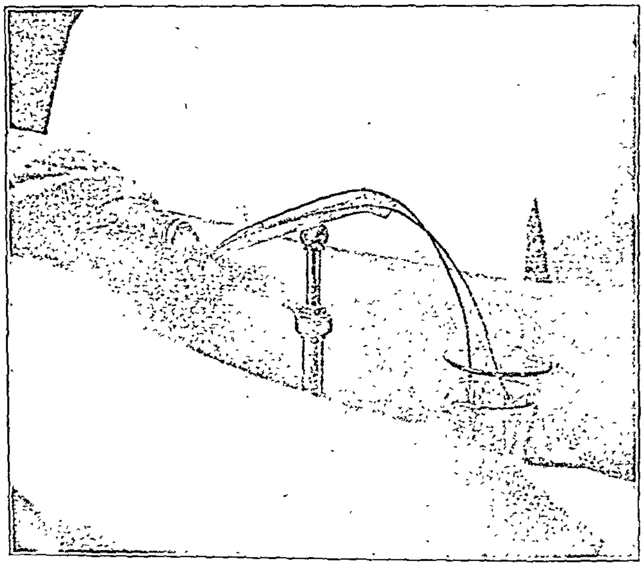

Fig. 2.—Patient in reclining posture for collecting urine through the ureteral catheters. Catheters running over elevated plane, dipping into glasses.

If after completed catheterization the intention is to leave one or both catheters in place for some time in order to collect urine, the patient's legs, after the removal of the cystoscope, are relieved from the stirrups, the foot end of the chair is raised and the patient is kept in a recumbent position. It is our practice to lead the ureteral catheters to their distal ends over an inclined plane that is carried by an adjustable stand.

In this way we avoid contamination of the collected urine through fluid coming out of the bladder that might run alongside the outer surface of the catheters. Fig. 2 shows all that clearly without further explanation.

We consider the small caliber of the instrument which we are using a distinct advantage. In the majority of cases it is absolutely unnecessary to resort to any local anesthetic. The application of cocain into the posterior urethra or into the bladder is always undertaken at a certain risk, because we have no means of gauging the idiosyncrasy for cocain or of counteracting an intense cocain poisoning.

In very sensitive patients we insert a morphin suppository into the rectum, ten minutes previous to the examination. This local morphin anesthesia furnishes another advantage over cocainization. The most disagreeable sensation is caused not by the contact of the instrument with the mucosa, but by the stretching of the parts. This disagreeable sensation is better dulled by morphin than by cocain. It remains to be seen whether the combined scopolamin-morphin narcosis might be used to advantage in cystoscopy. Often one succeeds in obtunding the sensibility of the posterior urethra and of the bladder by injecting a 4 per cent. antipyrin solution; it takes, however, about ten minutes before the anesthetizing effect occurs. Occasionally patients will develop a typical antipyrin rash after the application.

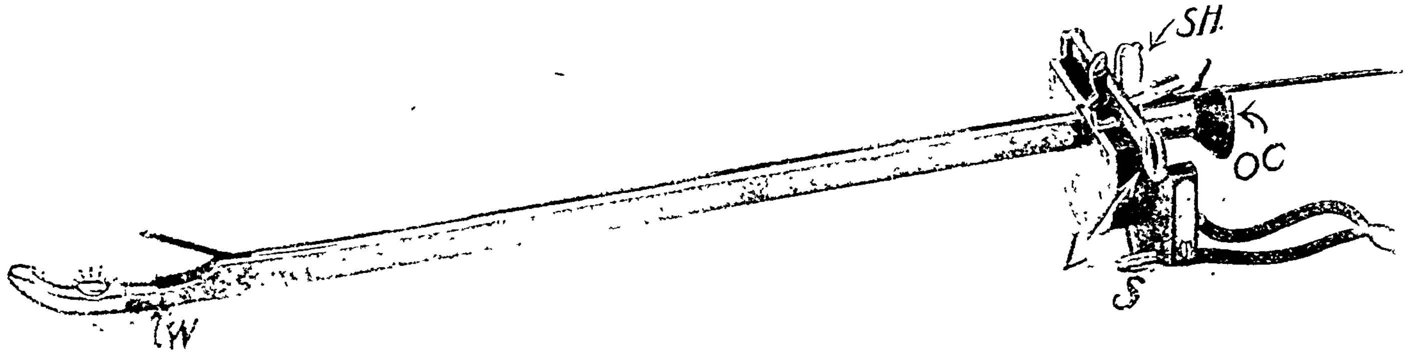

Fig. 3.—Casper's lastest cystoscope for ureteral catheterism. W. Window. S. Screw for fastening the lid. L. Lever for moving the shover. SH. Shover. OC. Ocular. The ureteral catheter is introduced into the conducting canal and protrudes at both ends.

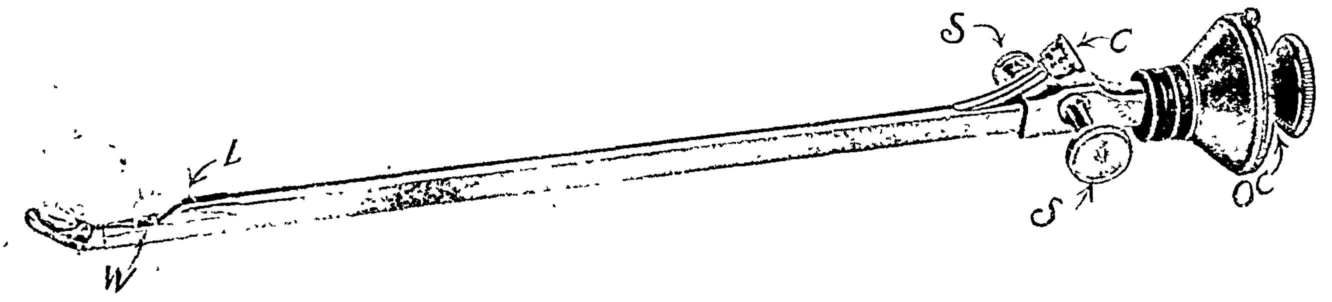

Fig. 4.—Nitze-Albarran single-barreled ureteral cystoscope. W. Window. L. Lever. Upper S. Screw for fixation. Lower S. Screw for directing the lever. C. Canal for catheter. OC. Ocular.

General anesthesia is required only in exceptional and extreme cases. In such cases it must be complete and deep, so as to prevent forcible contractions of the bladder, which might lead to rupture if the bladder is distended.

Under certain conditions in female patients we have to resort to a few special maneuvers in order to facilitate catheterization of the ureters. If we consider that a part of the fundus of the bladder is in close connection with the cervix, and that the trigonum rests on the anterior wall of the anterior fornix vaginæ, it is easily understood that dislocations of these parts will considerably interfere with the topographic situation of the trigonum. So far as the position of the cystoscope is concerned, the technical situation will simmer down to answering the question whether the trigonum is dislocated upward or pulled down toward the symphysis. In the former case the funnel or outer end of the instrument has to be lowered considerably, while in the latter case the funnel has to be elevated so that the whole instrument gets to be in rather a steep position. If a descensus or prolapsus exist it may become necessary to reconstruct a normal condition by packing the vagina more or less tightly after having replaced the parts. Once in a while it is important to catheterize the ureters in cases of vesicovaginal fistula, so as to get information as to the relation of the ureteral ampulla to the cicatricial tissues. If the fistula is rather small and its edges movable, we close the fistulas with small clamps, and in case of rigidity of the edges the vagina is packed tightly with wet absorbent cotton so as to prevent leakage for a considerable time, and to allow sufficient distention of the bladder.

The finding of the ureteral openings may be very difficult on account of inflammatory changes in the mucosa, as the whole trigonum becomes raw and covered in some instances with all kinds of fossetæ and recesses. In some cases we still succeed in discovering the ureteral openings by watching for the urinary whirl. We may be aided in this endeavor by coloring the urinary stream; best by subcutaneous administration of indigocarmin. But this watching for the urinary whirl is extremely tiresome for the eye because quite often the activity of the kidneys is entirely suppressed for a short period during cystoscopy. In some cases, in the female, we succeed by inserting a finger into the vagina and lifting up the anterior wall of the fornix so that the trigonum is brought very close to the cystoscopic window. Thus we are able to ascertain whether a certain recess is only a blind one or whether at its bottom the ureteral opening is to be found.

One may succeed in difficult cases in making more prominent the trigonum, the intraureteral ligament and the ureteral openings, by seizing the dome of the anterior vaginal fornix with a vulsellum and by pulling down *the fornix.*

A similar procedure as above mentioned may be used if the ureteral openings in the male are situated on the posterior side of a prostatic elevation. Quite often ureteral openings which are hardly visible, or even if visible can not be entered by the ureteral catheter, can be made practicable for catheterization by forcibly elevating the bas fond of the bladder through one or two fingers inserted into the rectum, or through the distention by a colpeurynter placed in the rectum. In cases in which the trigonum-mucosa is in a fluffy condition, hyperemic and easily bleeding, we are able to anemize it and make the trigonum practicable for examination by applying a few drops of adrenalin solution previous to distending the bladder. Such a condition is regularly found after the application of segregators.

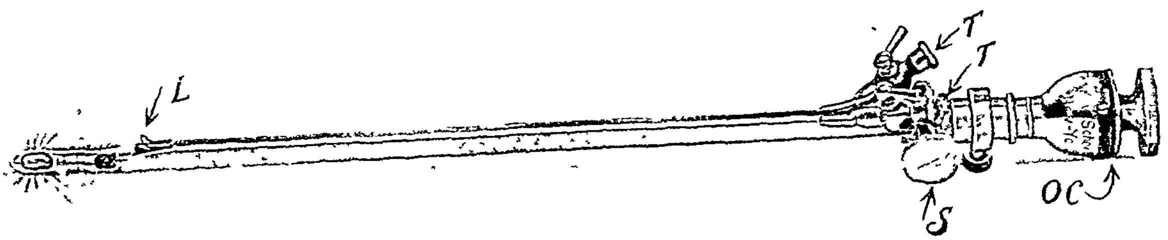

Fig 7.—Bierhoff's modification of double barreled Nitze-Albarran cystoscope The turnable tube carrying the conducting canal is rotated for 90 degrees around the shaft of the cystoscope. L Lever. TT Conducting tubes carrying cocks S Screw. OC. Ocular.

If the inflammatory changes are very pronounced, so as to prohibit the distention of the bladder to a sufficient extent, or, that on account of the condition of the trigonum it should be impossible to discover the ureteral openings, or if both these conditions are present at the same time, cystoscopy and ureteral catheterization has to be postponed until appropriate treatment has succeeded in improving the mucosa.

The cystoscopes for ureteral catheterization naturally divide themselves into those furnishing a direct or an indirect inverted view of the examined area.

All the instruments with indirect view are based on the ideas suggested by Nitze and Casper. The principle is to attach to the upper edge of the instrument a conducting canal for the catheter so that the end of this canal is located next to the window and the underlying prism so that the central end of the ureteral catheter will appear at the concave side of the beak. Casper made the upper wall of this canal movable so that it represents a longitudinal sliding base which can be used for directing the tip of the catheter (Fig. 3).

It is evident that the slide bar pushed forward will curve the catheter in the arc of a smaller circle, so that the catheter tip is directed at a greater angle from the longitudinal axis of the instrument. On the other hand, when the slide bar is withdrawn the protruding end of the ureteral catheter is permitted to direct itself in a large curve and hence more in the line of the longitudinal axis of the cystoscope. When the slide bar is removed from the instrument the ureteral catheter falls out of its groove in the cystoscope, and hence is entirely free in the urethra. Then the slide bar can be replaced and the groove reconstructed into the original canal and may be utilized again for the passing of a second catheter without removing the cystoscope or the first ureteral catheter. Albarran added to this cystoscope a little lever which is placed under the distal end of the conducting canal (Fig 4). A screw attached to the funnel end of the cystoscope directs the motion of this lever, which gives the catheter tip a more or less angular dip: this instrument has got the slide bar in Schlifka's instrument (Fig. 5). All these principles, except the slide bar, are applied to those instruments which carry two canals for inserting catheters in both ureters at the same sitting without withdrawing the instrument, the so-called double-barreled cystoscopes (Fig. 6).

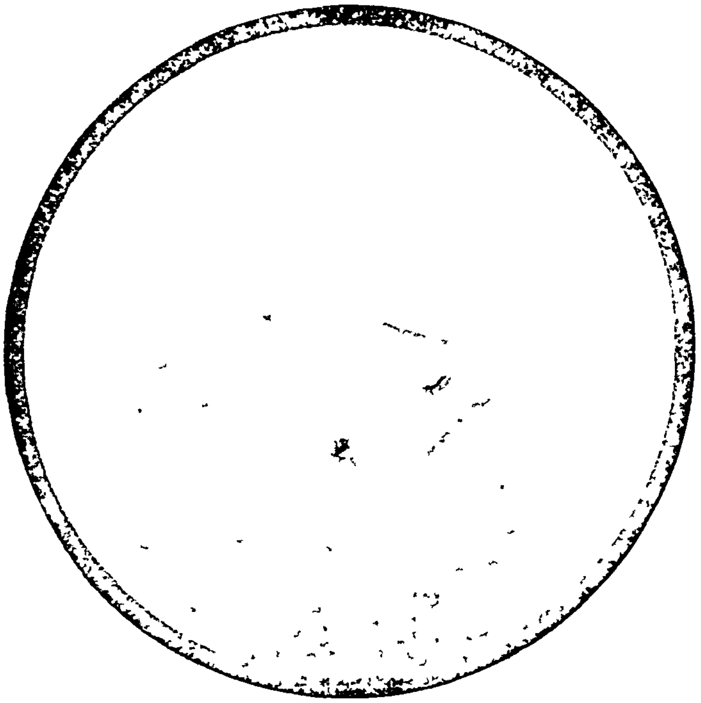

Fig 8.—Short trigonum

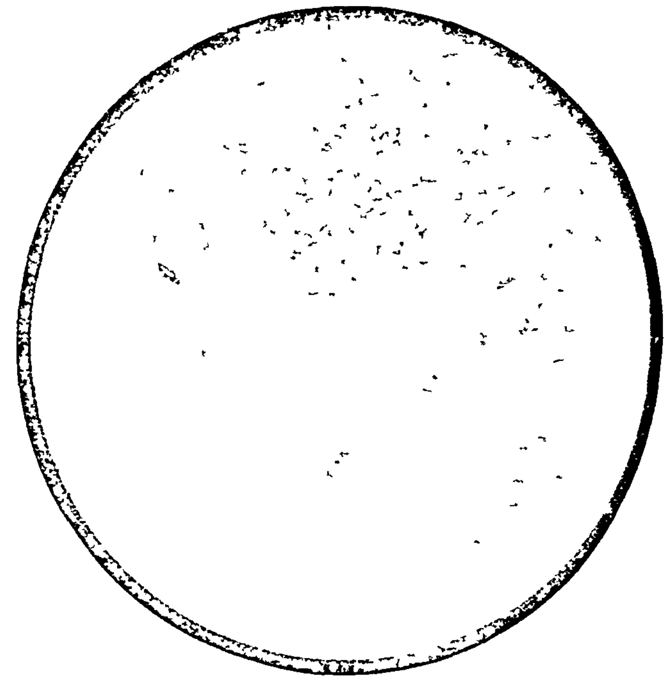

Fig 9.—Long trigonum

Bierhoff tried to improve on the double-barreled Nitze-Albarran cystoscope in a way; he made the attachment carrying the conducting canals revolvable around the shaft of the cystoscope (Fig. 7). After the ureteral catheters are inserted it is possible to turn the beak of the cystoscope again upward without disturbing the catheters in their location and position.

These instruments are used in the following way: After the bladder has been flushed out and filled (we do not limit ourselves to any specified amount of fluid, but dilate the bladder for ureteral cystoscopy to such an extent that the patient can bear it without discomfort), the cystoscope is introduced so that we are sure that the beak is freely movable inside of the viscus Now the electric light current is turned on and a sufficient intensity of light secured by inspecting the vertex of the bladder. This technic for securing the proper strength of light is better than to turn the beak to the trigonum immediately after its introduction and then gauging the light. After the light has thus been properly adjusted the beak is first turned toward the trigonum. In order to examine the trigonum closely it is necessary to lower the ocular end of the cystoscope. This movement of the cystoscope is the most disagreeable on account of the stretching of the suspensory ligamentous apparatus attached to the symphysis. Every movement of the cystoscope in this position is very keenly felt by the patient on account of the overstretched condition of the posterior urethra. If the cystoscope is left or kept in this position for any length of time the male patient becomes very nervous and restless.

In order to discover the openings of the ureters it will, if normal conditions prevail, be necessary to deviate with the beak of the cystoscope for about 45 degrees from the medium plane to the left or to the right, according to the ureteral opening sought for. This motion is accomplished by rotating the cystoscopic shaft in the forceps, which act as a handle. The following variations in the location of the ureteral openings occur in otherwise a normal trigonum.

Both the ureteral openings are located very close to the internal urethral orifice. This may be the case to such a degree that the ureteral openings lie inside of the funnel which is formed by forcing a cystoscope through the junction of the internal urethral orifice and bladder. Therefore it is a routine practice to start scanning the trigonum from the dark, red fold marking the internal urethral orifice. In some cases of this kind, it is necessary to dilate the bladder to the limit so that the ureteral orifices become practicable for the catheters. In cases of this kind we are often able to see the ureteral openings as transparent pink ovals, being illuminated from behind, while in any average distention of the bladder it would be impossible to catheterize them In such cases, then, the greatest distention of the bladder must be employed. This condition is called a short trigonum (Viertel) (Fig. 8).

Another variety is the so-called long trigonum (Viertel). Here the ureteral openings lie way inside of the bladder, and, as a rule, the frontal distance between them is a rather great one (Fig. 9). In the great majority of these cases the intra-ureteric ligament is well pronounced so that it runs as a prominent strand through the field of view, thus giving a prominent landmark, at either end of which the ureteral opening is to be found. Further abnormalities in the relative location of ureteral openings may be the following: While, as a rule, Nitze's remark comes true, that if one is able to locate one ureteral opening it is very easy to find the other one, because the ureteral openings are always situated symmetrically, still there are some exceptions. One of the more frequent is that one of the openings is located centrally just opposite the urethral orifice, the other one lies somewhere laterally (Fig. 10). This condition may always be suspected if the following symptoms complex is reported. Shortly after the bladder is emptied urinary calls set in, whose intensity decreases more and more with the time that elapses after urination, and disappears entirely with progressing dilation of the bladder until the normal limit of extension is reached. The bladder mucosa proper shows no signs of inflammation. This condition evidently has to be explained by the fact that the ureteral whirl, squirting from the ureteral opening lying opposite and close to the internal urethral orifice, strikes the sensitive urethral mucosa until the increasing dilation of the bladder places the centrally located ureteral opening more inside the viscus. Inflammatory conditions and others which are apt to change the normal configuration of the trigonum were discussed in the general remarks.

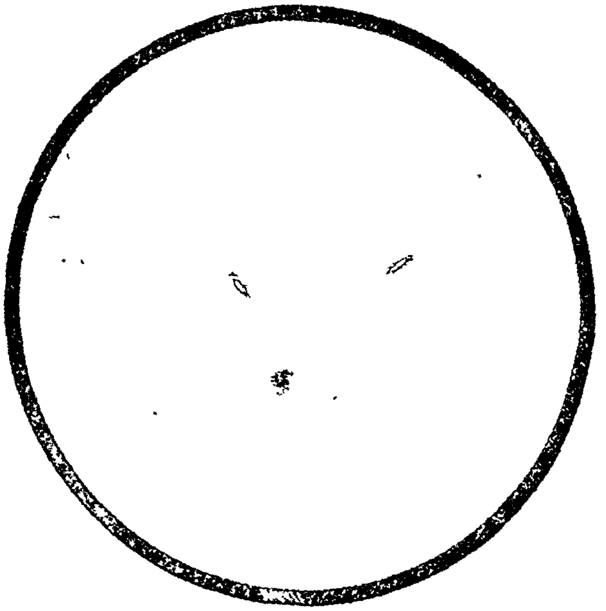

Fig 10.—Trigonum with one ureteral opening located opposite the urethral orifice

Summing up the features of the ureteral cystoscopes, we can say this: Up to a recent time it certainly was easier to find the ureteral openings through a cystoscope with indirect view than with those of direct view, but with the latter method the introduction of the ureteral catheter met with less difficulties than in the instruments of the indirect vision type. The ureteral openings are more easily found by the indirect vision instruments equipped with Nitze's lens system because, as a rule, they have a larger field of view, so that in every position of the cystoscope a larger area of the trigonum becomes visible and the illumination of the ureteral openings *from behind* is only possible with these instruments.

The insertion of the ureteral catheters is more difficult for two reasons. First, we are never able to bring the opening of the conducting canal of this type of instrument close to the ureteral mouth. That is apparent by looking at a drawing showing a cystoscope in position. The distance between the window of the cystoscope and the canal is necessarily a large one. Second, the tip of the catheter does not protrude into the bladder at an angle favorable for introducing it into the ureteral opening (Fig. 11). This latter condition was early recognized and resulted in the construction of the various contrivances intended to enable us to give the catheter end the various directions. The only commendable appliance for this purpose is Casper's sliding lid. Albarran's lever has some drawbacks. In the first place it necessitates an enlargement of the caliber of the cystoscope. Second, it increases the number of sharp edges at the concavity of the instrument. Third, if put in use it interferes quite often with the easy gliding of the catheter. Two features common to all ureteral cystoscopes of indirect view are very disagreeable. One is that inspection of the trigonum and insertion of the catheters can only be accomplished while the cystoscope is kept in a position which is uncomfortable to the patient. The other is that even the most refined workmanship can not prevent the sharp edges and nooks which are the consequences of the construction. The insertion of catheters in both ureters at the same sitting is explained by the notes attached to the respective drawings (Fig 12).

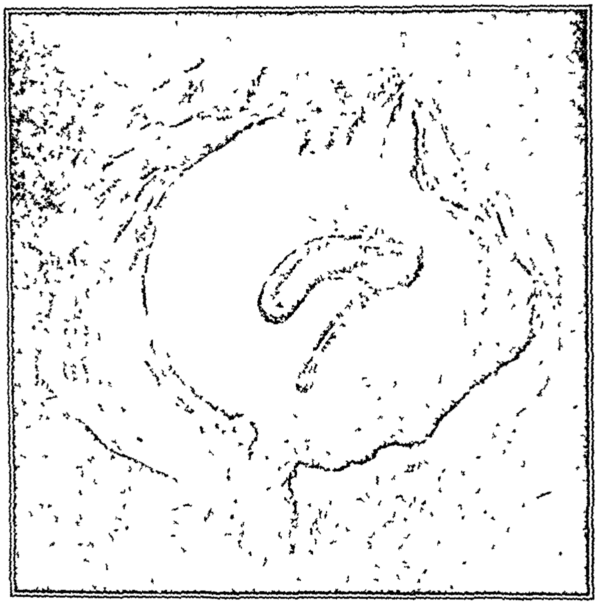

Fig 11.—Specimen of male bladder opened. Casper's cystoscope inserted, catheter sticking in ureteral orifice

Latzko and Mirabeau catheterize the ureters in the female by separating the conducting tube entirely from the cystoscope of indirect view. First the bladder is filled with water, then the conducting tube, armed with the ureteral catheter, is introduced. This accomplished, a very small Nitze examining cystoscope (children-cystoscope Fr. 18) is introduced, the ureteral opening focused and the catheter is inserted (Fig. 13).

Although the authors are rather enthusiastic about their method, there are serious disadvantages connected with it.

In the first place, the method is only applicable in women; second, the introduction of two instruments through the urethra is very annoying to the patient; the use of the children-cystoscope gives only a small field of view, so that even under slight pathologic changes in the trigonum the locating of the ureteral openings is rather difficult. Catheterizing both ureters at the same sitting is almost impossible, because withdrawing the conducting tube is almost invariably followed by a dislodging of the first inserted ureteral catheter, by the friction against the strongly curved tube.

The instruments of direct view are all built after a principle, first laid down by Brenner in the early 80's (Figs. 14 and 15). The cystoscope is a Nitze cystoscope No. 2, to whose lower edge a conducting canal is attached. The view is a direct one; the distance between the window of the cystoscope and the opening of the conducting canal is a minimum one (Fig. 16). If the ureteral openings are not too far apart they can both be located by bringing the beak in a parallel position to the trigonum. If, however, the ureteral openings lie further apart, lateral movements must be made. That is, we must deviate with the whole shaft of the cystoscope for between 25 and 45 degrees from the sagittal medium planum to the left, or to the right, according to the ureteral opening sought (Fig. 17). The inspection of the trigonum again begins at the internal urethral orifice. If an interureteric ligament is to be seen, one follows it either way until we discover the ureteral opening. As we are able to bring the opening of the conducting canal close to the ureteral mouth, it is absolutely unnecessary to give the catheter any special curve.

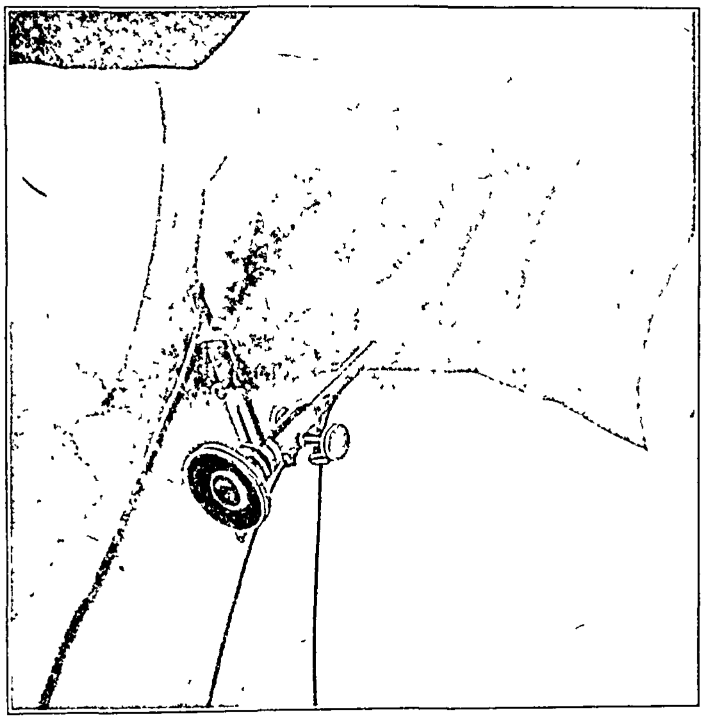

Fig. 12.—Patient with inserted double-barreled ureteral cystoscope of indirect view. Both catheters inserted into the ureteral openings. Notice the necessary lowering of the ocular end and the subsequent tension in the parts.

It is only in extremely rare cases where the ureteral openings are located beyond the crest of the trigonum usually containing them, that in some of these cases a slight curving of the ureteral catheter may be necessary. Then we use the following method: The beak of the cystoscope is withdrawn as closely as possible toward the internal urethral orifice and the catheter passed along into the viscus until it strikes the opposite bladder wall. By gentle permanent pressure the catheter tip glides down on the bladder wall and the catheter end retains, in the warm fluid, its acquired curve. If the cystoscope is again introduced as far as necessary to focus the ureteral opening, the catheter can now be inserted.

In other cases the ureteral openings lie absolutely in the same level as the trigonum mucosa, no ureteral crest being present. In cases of this kind the ureteral openings become practicable for catheterization by pressing downward the whole shaft of the instrument; by making a sort of a dipping movement with the beak the ureteral opening looms up and can easily be entered.

If we desire to withdraw the cystoscope and leave the ureteral catheter in place, we proceed in the following manner: One hand grasps the cystoscope, while the other, seizing the free end of the catheter, keeps on pushing it into the ureter, so that the catheter is forced inward at the same ratio, as the cystoscope is withdrawn. When the beak of the cystoscope and the protruding part of the catheter appear at the ureteral orifice, the catheter hand gets hold of the visible catheter loop and, while this is fixed between the tips of index and thumb, the other hand removes wholly the cystoscope (Fig. 18).

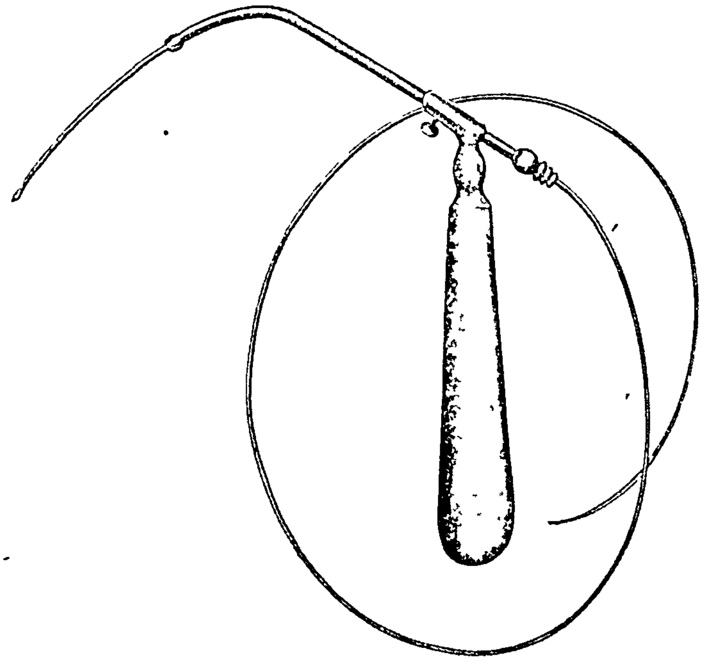

Fig. 13.—Latzko's instrument for ureteral catheterization. Ureteral catheter inserted into conducting tube.

This maneuver can also be employed, if we desire to catheterize both ureters at the same sitting, and we have at our command only a cystoscope that is not fitted with attachments especially adapted for this purpose. The cystoscope, after one ureter is catheterized, is withdrawn in the manner above described, and again reintroduced alongside the catheter lying in the urethra and protruding therefrom.

In the female it is important, however, to have the first catheter on the concave side of the beak in reintroducing the cystoscope for the second catheterism. In this way the first catheter is kept out of the field of view. If we neglect this little maneuver, the first catheter is forced into a loop in front of the cystoscope window, interfering considerably with the free view.

While the maneuver of withdrawing the cystoscope and reintroducing it, armed with the second catheter, is easily carried out in the female without inconveniencing the patient, the whole procedure, although not impossible, is rather awkward and painful in the male.

It therefore became necessary to modify the instruments with direct view in such a way as to allow the catheterism of both ureters at the same sitting in a more appropriate way.

For this purpose two principles are applied. The one is that a double-barreled conducting canal is attached to the lower edge of cystoscopic shaft.

The first instrument of this kind was constructed by Tilden Brown (Fig. 19); later on this principle was adopted in constructing double-barreled instruments to be used with air dilation. Types of these latter instruments are, for instance, Bransford Lewis' and Elsner's instruments (Fig. 20).

Tilden Brown's instrument is a double-barreled cystoscope built after Brenner's principle. The cystoscope, armed with the obturator, is introduced into the empty bladder. Now the obturator is removed, and the bladder flushed out and eventually dilated with a sterile transparent fluid through the hollow shaft of the cystoscope. After this is done, the optical apparatus is introduced into the shaft of the cystoscope. The optical tube carries the double-conducting canal, and before introducing this part of the cystoscope, both the ureteral catheters are inserted into the tubes. Now the light is turned on, the ureteral openings are focused and catheterized in turn one after the other. While it has to be admitted that in normal cases not much difficulty is experienced in catheterizing the ureters and in leaving the catheters in place after withdrawal of the instrument, the following disadvantages have to be noticed: The instrument, like all double-barreled cystoscopes, is of rather large caliber; the protruding sharp edges of the conducting canal easily produce hemorrhage and darkening of the field of view, if the trigonum mucosa is even slightly diseased. In case it is only possible to insert the ureteral catheters for a short depth into the ureters, withdrawal of the conducting tube will be followed by dislodging the inserted catheters.

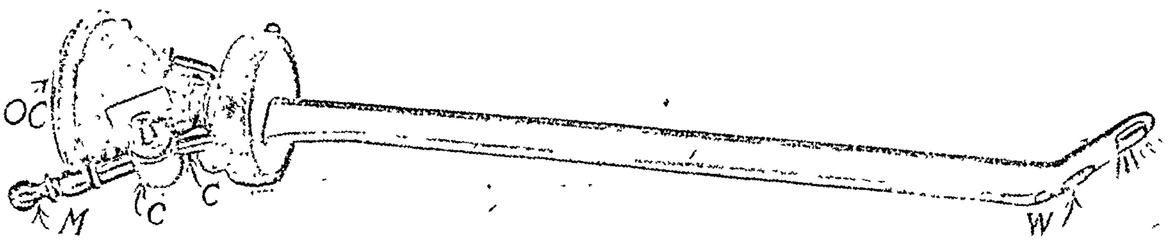

Fig 14.—Brenner's ureteral cystoscope. W. Window. CC. Conducting canal. M. Mandrin. OC. Ocular.

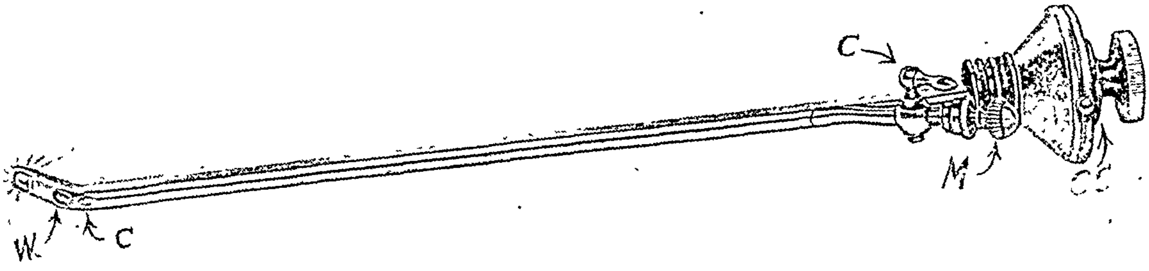

Fig. 15.—Brenner's ureteral cystoscope. W. Window. CC. Conducting canal. M. Mandrin. OC. Ocular.

Ayres of New York uses this instrument quite extensively, while Young of Baltimore has discarded it in favor of Casper's instrument. He very soon recognized the above-mentioned disadvantage, and after an attempt to get around these difficulties by some modification, he stopped using it entirely.

All the objections to the double-barreled conducting canal cystoscopes of indirect vision apply to the double-barreled conducting canal cystoscope of direct vision. The instrument can not easily be withdrawn, while the catheters are left in place for the purpose of collecting the urine separately for any length of time. The unavoidable large caliber of the instrument may cause great discomfort to the patient while in place. If the conducting canals are decreased in size the caliber of the instrument is reduced, but the caliber of the catheters that may be used are thus also reduced in size.

The other principle is taken from Casper's first instrument—the principle of having a part of the conducting canal removable so that the first inserted catheter can be thrown out, and after this the conducting canal can be reconstructed, so as to be ready for the insertion of the second catheter. The advantage of this principle is that the caliber of the instrument may remain within desirable limits; the instrument can be withdrawn after the catheters are inserted without disturbing them in their location. We are in a position to use even catheters with a funnel at their distal end. This is of importance, as it enables the operator to overcome an occasional plugging up of the catheter by injection of sterile water.

In this sense two types of instruments were constructed—a Brenner cystoscope with a movable tube in the conducting canal, and a Brenner cystoscope modified by the authors after Casper's principle.

The first-mentioned modification was made according to our suggestion by Snell of Chicago in this way: that into the conducting canal, open on the lower surface of the Brenner cystoscope, a metallic tube is inserted which can be easily withdrawn and replaced. With the tube in place the first catheter is inserted, then the tube is withdrawn over the catheter; either by turning the cystoscope to one side or by reinserting the tube, the first catheter is thrown out of the conducting canal into the urethra, and now the tube is replaced and ready for the insertion of the second catheter (Fig. 21).

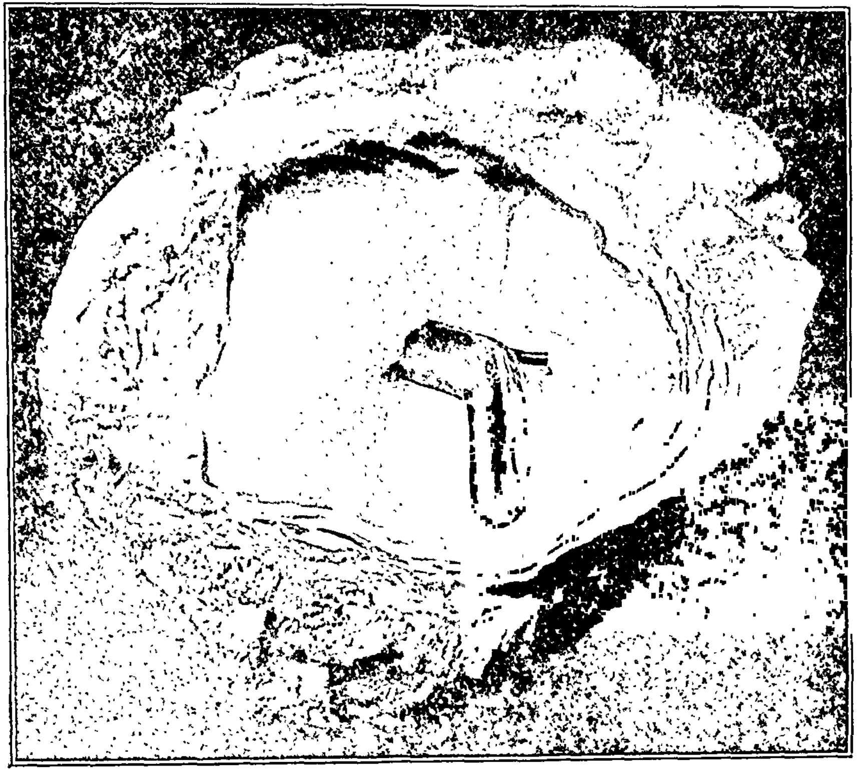

Fig. 16.—Specimen of male bladder opened. Brenner's cystoscope inserted and ureteral catheter in ureteral opening. Notice the minim distance between instrument and ureteral orifice.

This instrument works satisfactorily in expert hands, although two points are of a more or less pronounced disadvantage—the movable tube takes up quite a space, so that, if we want to keep the circumference of the instrument in proper limits, the lumen of the tube and consequently the caliber of the ureteral catheter must be very small. Second, the friction between the catheter and tube, particularly at the latter's curved distal end, is quite considerable, so that it requires great deftness of manipulation in order not to displace the first ureteral catheter in withdrawing the tube. Once in a while the dropping of the catheter meets with considerable difficulty.

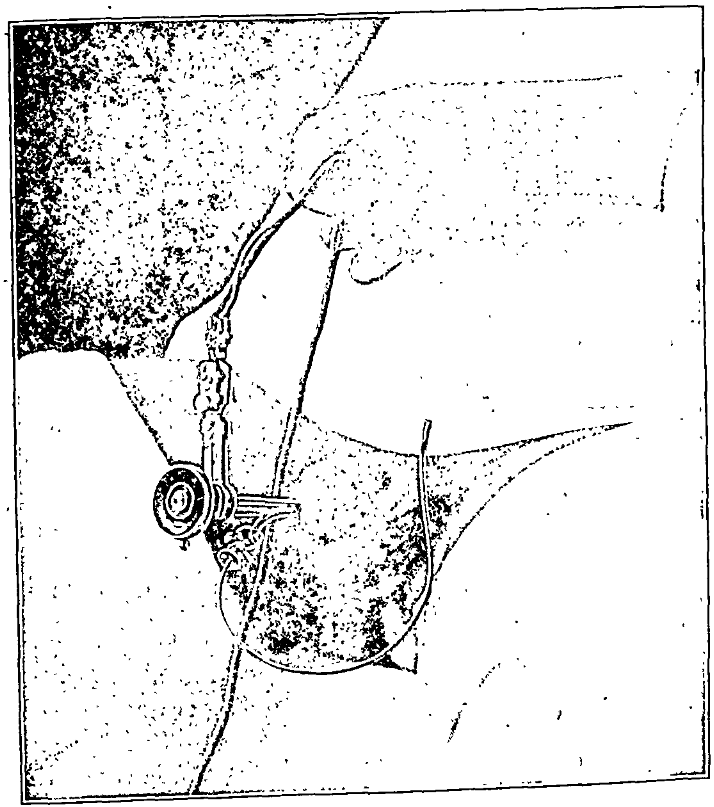

Fig. 17.—Patient with Brenner's cystoscope inserted; ureteral catheter in left ureteral opening. Notice the very slight tension of parts.

We believe we have succeeded in avoiding these inconveniences without sacrificing any of the advantages of this principle, by adjusting Casper's slide bar to a Brenner cystoscope (Fig. 22). Inasmuch as this slide bar is practically a part of the conducting canal, the latter can be wide enough to allow the passage of the largest sizes of ureteral catheters without unduly increasing the size of the cystoscope (its actual caliber is twenty-three French). After the first catheter is inserted into the ureter, the slide bar is withdrawn and the cystoscope is turned slightly to one side. In case the catheter does not slip out of the now open groove it is easily forced out by the reinsertion of the slide bar. Now the cystoscope is placed in position for the focusing of the other ureteral opening, and the second catheter is passed through the conducting canal (again constructed by the reinsertion of the slide bar). (Figs. 23 and 24.)

After the second ureter is catheterized, the slide bar is withdrawn, the second catheter is dropped into the urethra, and the cystoscope is pulled out of the bladder and urethra. There is no danger as to displacing the ureteral catheters, because the friction between the catheter and ureteral mucosa is con-

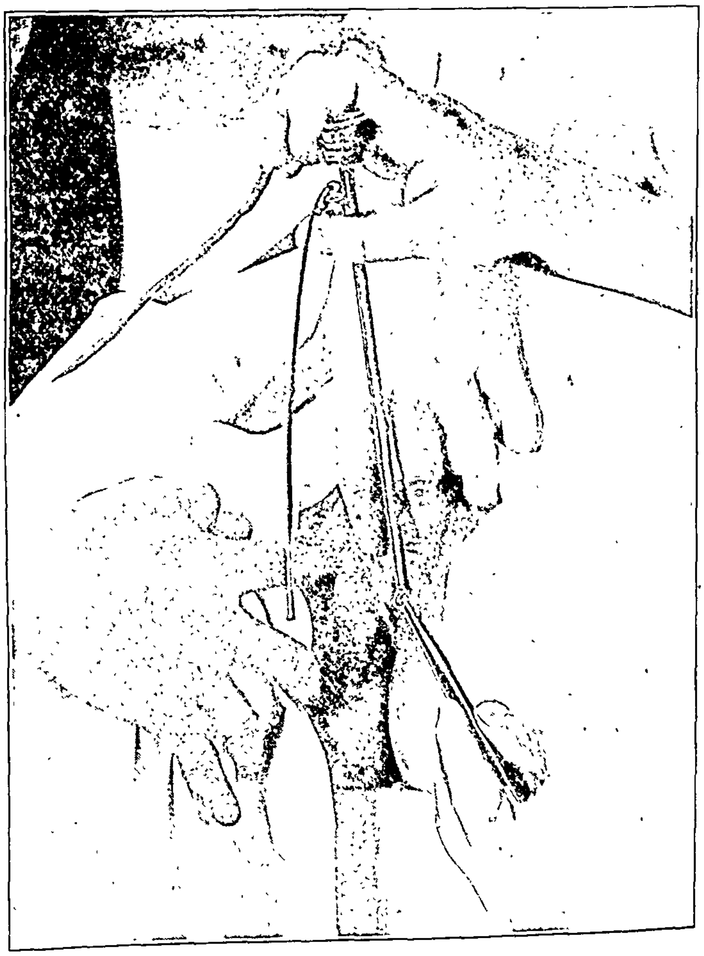

Fig. 18.—Female patient. Brenner's cystoscope almost withdrawn out of urethra, so that only its beak remains in urethra. The loop of the ureteral catheter just appears before the orifice and is caught by the tissue forceps as preliminary act before entirely withdrawing the cystoscope over the catheter.

siderably greater than the adhesive force between the catheters and the smooth metallic surface of the cystoscope (Fig. 25).

We are confident that we are now in possession of a ureteral cystoscope with direct view, that is of convenient size and allows of catheterizing both ureters at the same sitting, and allows of leaving both catheters in place, after the cystoscope is removed. It furthermore permits the use of catheters with injection attachment at the distal end.

In regard to the choice of ureteral catheters and sounds the following considerations are decisive: If we endeavor to simply test the patulence and permeability of a ureter, we use a metallic elastic, flexible sound; if we at the same time search for a stone, we cover the tip of the sound after Kelly's suggestion with wax, or produce a thin covering by dipping the end of the metallic sound in bichlorid solution (1-500), so that scratches may become visible. They are more distinct by examining with a magnifying lens.

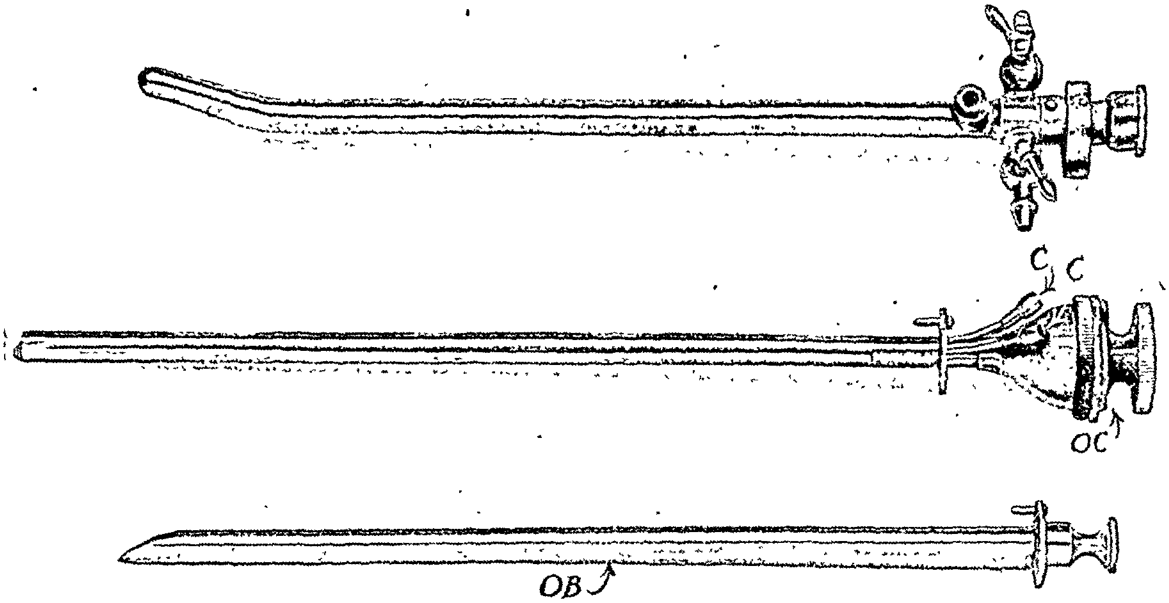

Fig. 19.—The Tilden-Brown double-barreled catheterization instrument. CC. Conducting canals. OC. Ocular. OB. Obturator.

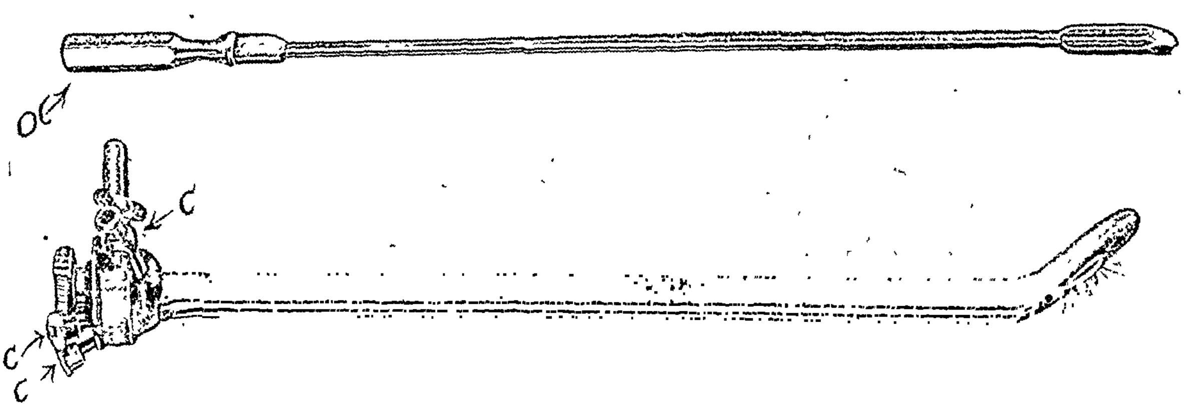

Fig. 20.—The Bransford Lewis instrument of direct view. CC. Conducting canals. Upper C. Cock. OC. Obturator.

If one intends to make injections into the renal pelvis, one uses catheters with a centrally located opening; for the collection of the urine and for injection in the ureters, one employs catheters with a lateral eye. In former times great value was placed on certain olive-shaped catheter ends; experience has shown that it was an unjustifiable inference. In collecting urine from patients whose ureters or kidneys are the seat of suppuration, the catheters easily become plugged up; injection of a few cubic centimeters of fluid will remove the obstruction. To employ suction through an attached syringe is a rather precarious procedure, because of the danger of sucking in a mucosa fold and of aspirating blood in this way.

If one wants to get information on the course of the ureters and the topography and size of the renal pelvis, one employs lead wires for sounding; their ends have to be smoothed by melting.

If it is desirable to measure distances, to ascertain how deep the catheter is inserted into the ureter, we use so-called zebra catheters. The covering of these catheters is graded in yellow and black fields in turn, each field one centimeter long; by counting the number of colored segments that disappear into the ureter, the distance can easily be measured (Fig. 26).

It is expedient to lubricate the catheters before introduction, either with glycerin or Casper's lubricant. In this way we secure an easy gliding and prevent at the same time injury to the ureteral walls. The lubrication at the same time prevents the bladder fluid from running alongside the surface of the catheters.

In case one draws blood through one catheter shortly after insertion, Casper suggests to move up the catheter tip a little farther; if the bleeding come from an injury of the ureteral mucosa, produced by the catheter, the catheter eye passes above the place and the hemorrhagic tinging of the urine will disappear.

It is a good plan to mark the catheters in some way, so as to be sure into which ureter each of them leads. We either select catheters of different color, or tie one of them, after application and eventual removal of the cystoscope, in a loose loop.

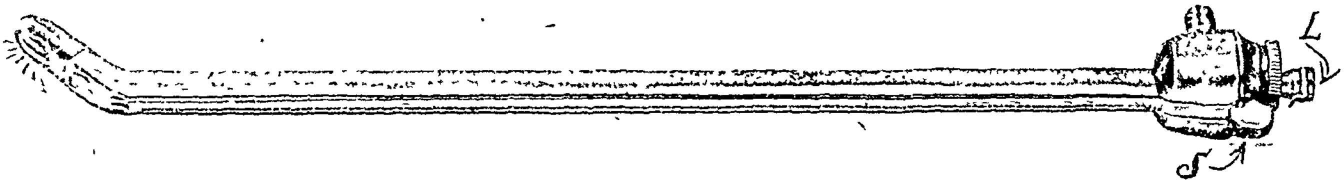

Fig. 22.—Kolischer-Schmidt's modification of Brenner's instrument S Slide bar. L. Lens system.

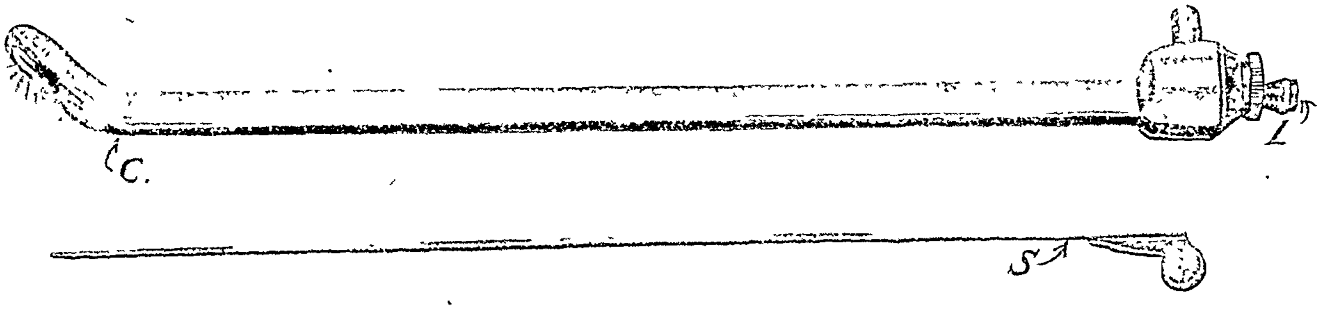

Fig. 23.—Kolischer-Schmidt's instrument. Slide bar withdrawn. C. Conducting groove. L. Lens system. S. Slide.

If there should be any doubt as to the sterility of the bladder mucosa, we disinfect the viscus previous to cystoscopy by irrigating with a silver-salt solution. After completed cystoscopy, it is a routine practice to flush again with a non-irritating silver-salt solution or to instillate a few drops of a concentrated solution.

Peculiar difficulties may arise if a ureter does not allow of passing a catheter or sound to any depth. The reasons for this may be twofold. Either the mucous membrane is in such a condition that it obstructs the passage or the ureter is distorted in such a way that its meandering loops do not let pass a catheter or a sound that is not very stiff. The last-mentioned condition will occur most frequently after gynecologic operations that lead to changes in the topographic surroundings of the ureter. We succeed, however, in entering the ureter in such a case by using metallic sounds. Quite often this sounding is facilitated by injecting sterile oil previous to the attempt.

Swelling of the ureter lining, if only due to infection and inflammation, can easily be overcome for the time of sounding by instillating a few drops of adrenalin solution. The mucosa is enemized for some time. The obstruction is in this way removed, and the catheter or the sound is easily passed along.

If, however, the swelling of the ureteral mucosa is due to traumatism, conditions are entirely different. Tears in the mucosa or bloody suffusions catch the catheter tip, and any forcible attempt of passing the catheter leads to further laceration of the mucosa. These traumatic injuries to the ureter and mucosa are either due to awkward attempts of catheterization or to the passing of a large or sharp-edged kidney or ureteral stone. In such a case we have to wait for some time until the injuries have healed up. We might enhance this process by the application of iodoform solutions.

Some of the cystoscopes can be sterilized by boiling, especially those of American make that do not have any windows closed by a glass plate. All those cystoscopes that are fitted with cemented glass windows and silver-plated prisms do not stand boiling. These instruments have to be rendered sterile in the following way: They first are scrubbed with tincture of green soap, afterward rinsed with sterile water and then dried with sterile gauze. Then they are suspended and kept in a glass chamber permeated by formalin vapors. If one wishes to add an additional precaution, the cystoscope before use is submerged for some time in a 3 per cent. carbolic-acid solution. All this scrubbing and submerging can be done without injuring the lens system, because the modern instruments are fitted with a metal cap that can be screwed over the ocular.

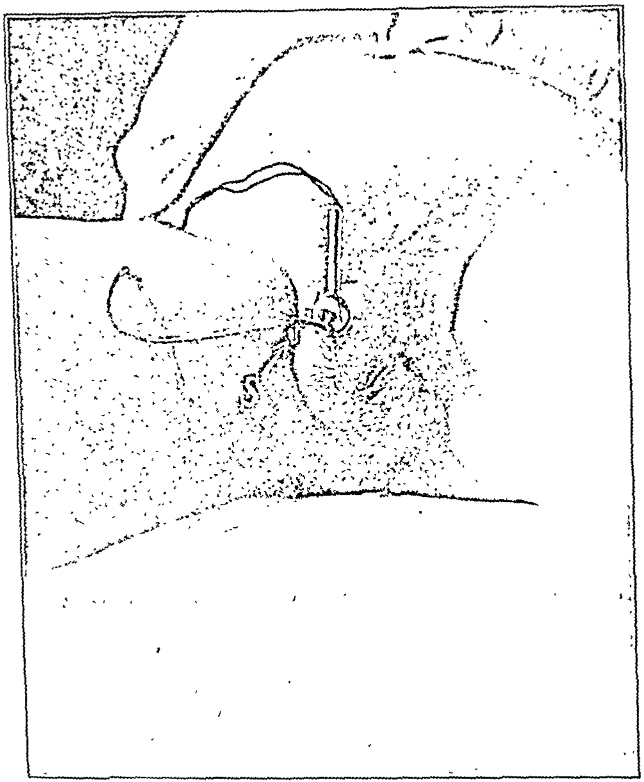

Fig. 24.—Kolischer-Schmidt's instrument inserted into patient. Catheter inserted into left ureter, slide bar half way withdrawn. S. Slide bar.

The sterilization of the ureteral catheters should be done in a different way. If a sterilizer with high pressure and live steam is at command the catheters can be sterilized in this manner: After they are taken out of such a sterilizer they are to be kept in a glass tube, in which formalin vapors are constantly developed. If such a sterilizer is not to be had, or if sterilization has to be accomplished in a very short time, the catheters are boiled in water. In this case the catheters have to be carefully wrapped in gauze so that no two surfaces of the catheter come in contact, otherwise the catheter loops become glued together and the catheter is ruined. It is our practice to put the catheters immediately before use into a 1-1000 bichlorid of mercury solution; before insertion into the cystoscope they are rinsed with sterile water and lubricated with glycerin. Metallic sounds are simply boiled before use.

When the urethra of the patient is suspicious of pathogenic germs, it is to be irrigated with antiseptic solution previous to cystoscopy. As a mere matter of routine, this should be done in all cases. Besides have the patient take 0.25 gram urotropin four times a day for some days previous to ureteral catheterization.

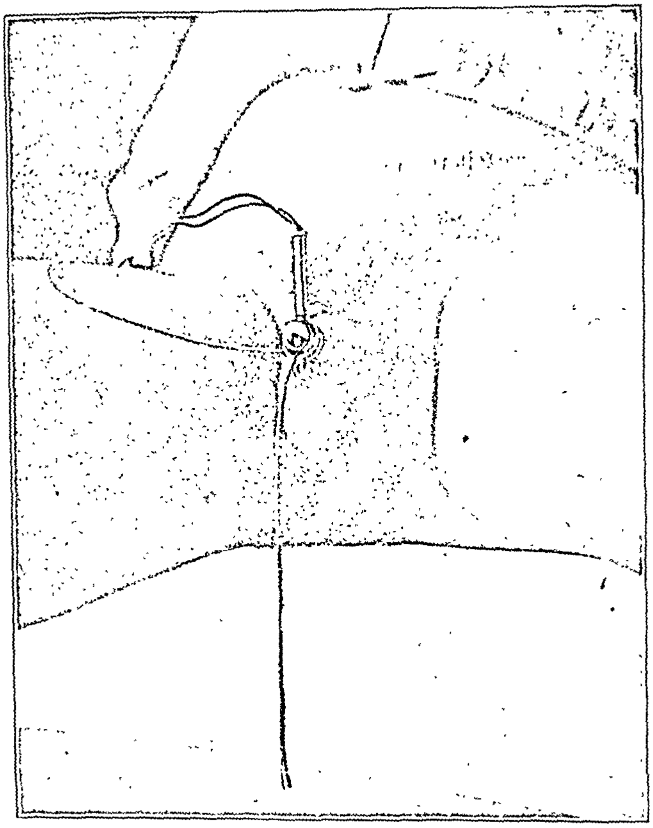

Fig. 25.—Kolischer-Schmidt's instrument inserted in the patient. Catheter inserted into right ureter, thrown out into the urethra. Instrument ready for catheterization of the left ureter.

The same surgical cleanliness has to be as strictly enforced by the operator and his assistants as in any other aseptic surgical interference.

The Small Medical School.—Osler says that the day has passed in which the small (medical) school without full endowment can live a life beneficial to the students, to the profession, or to the public.

THE BUSINESS SIDE OF A PHYSICIAN'S LIFE.*

H. BROOKER MILLS, M.D.
PHILADELPHIA.

. . . So far as reviewing the work of the past year is concerned, I would only like to call your attention to the excellent work done by both the scientific business and membership committees, together with the faithful work of the secretary and the hearty co-operation of the members. I feel that our programs have always been a credit to the society; our attendance has been on a gradual increase; our membership roll has increased rapidly, and our benefit to the profession at large has been more felt than ever before. That the branch movement in the county medical society was a good one, has been well proved by the past two years' work of our own branch, and not only has it been the means of causing a great deal of good work to be done, but it has also shown us in what direction much more needs to be done. The experience of the last two years has borne excellent fruit in the way of organizing the medical profession in this city, as well as stimulating its organization in other parts of the country, and I feel the work already accomplished probably far exceeds the expectations of the prime movers in this work, both of whom have been and are ardent supporters of our own branch, i. e., Drs. Eaton and Hirsh.

I thought I would discuss for a few moments this evening the subject of physicians' relations, and desire to do so under the heading of relations to, first, their patients; second, their fellow-members of the profession, especially consultants; and last but not least, to themselves.

As to the physician's relations to his patients, the views are so widely different and the relevant subjects so numerous that any concise expression of opinion is out of the question, but after conversing with physicians and the laity on the subject, I have come to the conclusion that much misunderstanding frequently exists between the physician and his patient as to the proper relation the one bears to the other, sufficient in many cases to work to the detriment of the patients. Such questions as the following all have a bearing on the subject under discussion:

Should a physician go out at night to treat a case in a family already owing him a large bill without any prospect of payment?

Should he treat a case recently involuntarily given up by another physician, when, in his opinion, the other physician has been unjustly discharged?

Should he adopt any of the measures commonly used by business men for the collection of his bills?

Should he undertake to treat at home, amid unfavorable surroundings, the cases which positively need hospital treatment in order to have any chance of recovery?

Should he regulate his charges according to the means of the family treated?

In fact, these have so much bearing on the subject that the last-named query has been frequently a subject of discussion in both the medical and lay press very recently. To decide these questions, the physician must either act as a physician or as a man, and his decision will be widely different, depending on which point of view he takes. While I know of cases where the purely human side has dominated, frequently to the physician's loss, yet I am sure that there are many where a purely medical side has decided the matter, not unfrequently to the patient's loss. The great question to my mind is: Can not the two sides be so commingled diplomatically that at least, in a majority of cases, neither side is the material loser? And I have come to the conclusion that the solution of the problem lies in one thing, and that is the training of the patient by the physician, which I admit is more an art than a science. In many cases the properly trained patient can be induced to avoid allowing bills becoming too large, often obviate calling the Doctor late at night, and not to become dissatisfied on slight provocation, and seek advice elsewhere on the spur of the moment, and I know of several prominent physicians in this city who can personally testify to the great advantages to be derived from what they term "The Training of the Patients." Particularly is this true in reference to the question of fees, and many of the controversies, especially such as have frequently become public on the question of charge, could be avoided, did the physician, in the first place, possess, and in the second, make more intelligent use of, a sufficient amount of business knowledge to practically as well as scientifically deal with the sick.

As to the second point, that of the physician's relations to the fellow-members of the profession and especially consultants, this again is a broad subject and one which is capable of much abuse. Did we but act and feel at all times toward our fellow-practitioners as we do toward our patients and were we always as anxious to retain the esteem of the former as the good will of the latter, I feel we should frequently be much more considerate in our expressions and more liberal in our views. In the same way as some of our poorest patients have proven to be our best practice builders, some of the apparent unknown members of the profession have proven to be the stepping-stones to at least fortune, if not fame, of some of the leading members of the profession to-day.

It is, therefore, a matter for serious thought as to, 1, the time to ask for consultation; 2, who to ask for, and 3, what shall be done with the fee.

I personally feel entirely incompetent to express any weighty opinion on this subject, but if data obtained by conversation, correspondence and reading, plus a small amount of experience count for anything, it certainly does enable me to express the opinion that the consultant's fee belongs to him and him alone. Here, again, arises the question as to the fee to be charged, and it does seem to me only justice that the consultants should be willing to consult for whatever fee the attending physician believes to be the maximum of the patient's ability to pay, and this once agreed on, should be looked on as the property of the consultant exclusively. A question not unfrequently asked, where this fee is not paid at time of the consultation, but is made to form part of the total bill for services rendered for that illness, is, should the attending physician pay the consultant in full out of the first moneys received, or divided out *pro rata* between the consultant and himself? And as much data as I have been able to collect on this subject, when boiled down yields a majority opinion in favor of the first proposition, i. e., the full as well as prompt payment of the consultant. This seems only fair, when one considers that should nothing ever be paid for any of the services rendered, the attending physician would not feel under any obligation to personally pay the consultant, which I think is an additional reason why the latter should receive his fee out of the first payment made.

---

* Address of the retiring chairman of the North Branch of the Philadelphia County Medical Society, Jan. 14, 1904.

The third and last question, that of the physician's relations to himself, would probably be more carefully expressed if it was called "his duty to himself." The overworked, partly fed and half-rested physician can not do justice to those entrusted to his care, nor is his zealous application to the relief of the suffering of others sufficiently understood to be appreciated by a large majority, especially of the suffering laity. The natural inborn selfishness of the human race, plus, as before mentioned, the lack of a proper training, added to more or less pain, not only obscures keen perception, but also benumbs the highest sensibilities of the rights of others sufficient to make very arduous if not well nigh impossible the satisfactory filling of the duties of the medical practitioner of to-day. In brief, the conclusion from this third and last question is that the medical man of to-day should make himself more a living example of the fruits of preventative medicine, in order to better fit himself to practice the art of scientific mediicine.

In concluding this brief and as yet incomplete address, I desire to thank the members as sincerely and heartily for their uniform courtesy and kindness to me during my term as chairman, as I did and do again for honoring me with the election one year ago, and to take the liberty of asking for my successor a continuance of that same leniency and consideration, which has enabled one so poorly fitted for the position to close his term of office with the branch in such a satisfactory condition as the North Branch is to-day.

SURGICAL TREATMENT OF PULMONARY ABSCESS.*

VAN BUREN KNOTT, M.D.
SIOUX CITY, IOWA.

As the surgical treatment of pulmonary abscess still presents many difficulties to be overcome and problems for solution, the personal experience of operators in this line of work, even though that experience is limited, will be of assistance in formulating rules for future guidance.

No résumé of the literature will be attempted, as several scholarly articles published during the past two years have anticipated and rendered unnecessary such a procedure.

Experience has demonstrated that multiple lung abscesses and those accompanied by bronchiectasis are, as a rule, not benefited by operation. Tubercular abscesses and those due to the presence of a foreign body in the lung will not be considered, as they present complications placing them in classes by themselves, and with their surgical treatment I have had no experience. Metastatic and embolic lung abscesses are multiple and not amenable to surgical treatment.

This leaves for our consideration those cases of single pulmonary abscesses the sequelæ of pneumonia, with which may also be included those rare cases due to rupture into the lung of abscesses of the liver, those of appendicular origin, etc. These may be roughly divided into two classes, acute and chronic, and may or may not be accompanied by gangrene and bronchiectasis. As the mortality following surgical treatment of cases so complicated is fully twice as great as that of the simple cases, it is urged that these patients be given the better chance which is offered by timely surgical intervention.

With the general symptoms and diagnosis of pulmonary abscess there exists equally general familiarity. The surgeon will not, as a rule, see these cases until the diagnosis has been made by the internist, who has been in attendance and will be called on not so much to make a diagnosis of abscess as to determine its exact location, with the hope of surgical relief. This may be at times extremely difficult and often impossible.

In two cases which I have seen and which will be referred to again, although the patients presented all the symptoms common to abscess of the lung and the physician in attendance, as well as I, was satisfied of its existence, we were only able to locate it in the one case at the autopsy, and in the other suffered the indignity of having our diagnosis confirmed and our failure to locate the abscess accentuated by its rupture into the pleural cavity with empyema as the penalty.

While in many quarters attempts to locate the abscess by aspiration have been denounced as unsafe and injudicious, my limited experience has taught me the inadvisability of attempting to open an abscess of the lung without the aspirator as a guide. The physical signs common to this condition in many cases are alone not sufficient to render its exact localization possible, and, while we may be satisfied that in a given instance the lung contains an abscess and from the usual methods of examination have decided as to its location, this point should be positively corroborated by the aspirator before proceeding with the operation. In Case 2, reported below, I was so certain of the existence of an abscess in the lower lobe of the left lung that, despite my failure to locate it with the aspirator, I exposed the suspected area and subjected the patient to a severe and prolonged operation during my fruitless search for the pus. Fortunately, in the greater number of these cases, pleural adhesions are present so that unless repeated punctures are made, some of which may be beyond the area so protected, the danger of extravasation is slight.

In cases where the history and physical signs lead us to suspect pulmonary abscess, the localization must be made as accurately as possible by the usual and well-understood methods of examination. The patients should then be prepared for operation, and under local anesthesia an attempt to aspirate the abscess is made. The aspirator, which should carry a short needle of good caliber, should be introduced at the center of the suspected area, as at this point the protecting adhesions are most likely to be present. If pus is not found at this first attempt the needle should not be withdrawn completely from the lung, but as nearly so as possible and reinserted in various directions until it enters the cavity. This will prevent the multiple punctures of the pleura and diminishes the danger of extravasation of septic material into the pleural cavity.

When pus is found the needle should be left as a guide and chloroform administered, it being in the class of cases under consideration preferable to ether. A free incision, rendered so by the partial resection of at least two ribs, should then be made, well exposing the diseased area.

Pleural adhesions will usually be found present over the surface sufficiently large for the purpose. If absent the pleura must be sutured with catgut, using the common "back stitch." The suture line is then reinforced with iodoform gauze packing and the operation may be finished at the one sitting. This walling off of the pleural cavity may usually be effectually accomplished as above described and is preferable to postponing the second part of the operation in these weakened patients. If, owing to the extreme friability of these tissues, such suturing is impossible, because of the constant tendency of the stitches to tear out, the walling off must be accomplished by gauze packing and the operation deferred until sufficiently firm adhesions have formed.

---

*Read at the Thirteenth Annual Meeting of the Western Surgical and Gynecological Association, held at Denver, Dec. 28-29, 1903.

As, in the absence of adhesions, collapse of the lung may occur, it is advisable to have at hand for immediate use the Fell-O'Dwyer apparatus.

For the purpose of opening the cavity in the lung I prefer a probe-pointed pair of coarse dressing forceps, which are introduced alongside the needle into the cavity and the blades slightly separated. After the pus has been evacuated the opening may be cautiously enlarged by still further spreading the forceps, until of sufficient size to permit the examination of the cavity by the finger. Bands of tissue running across these cavities frequently carry large vessels and must not be carelessly torn loose.

The cavity should now be thoroughly wiped out with pledgets of gauze. Irrigation should never be employed. Tubular or gauze drainage have both been used. I use a flaring, cigarette, iodoform gauze drain, that is, one so constructed that the rubber tissue comes not quite to the end of the gauze, which may be spread to loosely fill the cavity, the rubber preventing the sticking of the gauze to the external portion of the wound. This is changed as the case demands, and must never be permitted to act as a "stopper," "corking up" the wound secretions. This device has answered every purpose and has been better tolerated than the tubes.

If gangrene is present the gangrenous tissue should be snipped away with scissors as carefully and completely as possible, the rest of the treatment differing in no way from that above described. The after-treatment is governed by the usual surgical principles.

To return to the aspirator. If after careful, thorough and systematic search pus is not found by this instrument, further operative interference should be abandoned, so that the patient may be spared the danger and uncertainty which it entails. I report the following cases:

Case 1.—H. C., boy, aged 12. I was asked to see this boy by his attending physician, who had already made a diagnosis of abscess of the lung following a severe lobar pneumonia seated in the upper portion of the left lung. The patient presented the history common to such cases. Examination disclosed the physical signs of an abscess occupying the middle external portion of the upper lobe. The patient was prepared for operation, and under local anesthesia a good-sized aspirating needle was introduced at the center of the suspected area, in the axillary line. The first puncture was negative, but after four or five attempts, slightly changing the direction of the point without completely withdrawing it from the lung, pus was encountered. The needle was left *in situ* and a U-shaped flap raised. This flap was buttonholed to permit of its retraction over the needle and this opening, being subsequently enlarged, was employed for drainage.

Portions of two ribs (about two inches) were then resected. The pleura being adherent a large, probe-pointed dressing forceps was then passed in alongside of the needle, and at the depth of an inch entered the abscess cavity.

About two and one-half ounces of pus were evacuated. The forceps were then spread slowly until it was possible to pass the finger into the cavity, which was then wiped out with gauze. Hemorrhage was slight. The cigarette drain, constructed as described above, was then introduced and brought out through the buttonhole in the center of the flap. The flap was then sutured in place and moist dressings applied. After seventy-two hours the drain was removed and a fresh one inserted daily thereafter. The cavity closed rapidly and the boy made an uneventful convalescence.

The operation in this case has been described rather at length, as it was closely followed in the remaining cases and will not be again detailed. Especial attention is called to the buttonholing of the flap, which allows of its withdrawal over the needle, furnishes ample drainage and permits of the restoration of the parts by suture.

Case 2.—Mrs. G., aged 37, was seen with her physician, who had diagnosed pulmonary abscess subsequent to pneumonia. The history seemed typical of this condition, and examination revealed the usual physical signs of an abscess in the lower portion of the lower lobe of the right lung. Careful and prolonged search with the aspirator failed to find pus. As we were certain the abscess existed, and thought the pus might be too thick to enter the needle, the lung was exposed as in the preceding case. Pleura was adherent and a pair of dressing forceps was thrust into the lung at the center of the suspected area. No cavity was encountered, but a profuse hemorrhage ensued, which was controlled with difficulty by gauze packing and the wound closed. The patient's symptoms were all aggravated after the operation until her death, which occurred ten days later. At the autopsy a large abscess cavity was found occupying the lower lobe of the lung posterior and external to the spot suspected by us. I consider that I made a serious mistake in persisting in the attempt to give operative relief after failing to locate the abscess with the aspirator.

Case 3.—Mrs. H., aged 40. I had made a hysterectomy on this woman some weeks previously, removing a large myomatous uterus. The third day following the operation she developed a lobar pneumonia involving the base of the right lung. This pursued a rather severe course, and was not marked by the usual crisis. Soon symptoms of sepsis developed, and we were forced to the conclusion that pulmonary abscess existed as the signs of its presence became more pronounced. Several attempts were made by the consultant and myself to locate the abscess, by the usual examination and with the aspirator, with failure each time. After two weeks of this uncertainty the abscess ruptured into the pleural cavity, this accident being rapidly followed by empyema. The usual surgical treatment was immediately employed, and after a most prolonged and tedious illness she made a good recovery. My chagrin at failing to locate the abscess in this and the preceding case may be better imagined than described.

Case 4.—John B., aged 22, was seen with his physician, who had made the diagnosis of abscess of the lung secondary to pneumonia. The patient presented the usual history of such cases. Examination pointed to the presence of an abscess in the lower lobe of the left lung. After the usual preparation an aspirator was inserted about the middle of the lobe and slightly anterior to the axillary line. At the first attempt pus was found. The operation was then proceeded with as in Case 1, the pleura being adherent. The cavity was somewhat larger than in the first case and contained about three and one-half ounces of pus. Subsequent treatment was same as Case 1. Recovery was apparently perfect.

As the treatment of these cases by other than surgical methods promises so little, and as the complications of gangrene, empyema and bronchiectasis so seriously increase the mortality, even in the hands of the best operators, it would appear that a plea made for early operative relief of patients suffering with pulmonary abscess is not inconsistent with the facts.

Note.—The completion of the paper of Dr. Murphy, begun in the last issue, is unavoidably postponed.

Saw Wood.—Let us cultivate the gift of taciturnity and consume our own smoke with an extra draught of work, so that those about us may not be troubled with the dust and soot of our complaints.—*Osler*.

Special Article.

THE ARMY MEDICAL DEPARTMENT.

V.

MEDICAL SUPPLY TABLES FOR THE ARMY.

(Concluded from p. 1419.)

If the average physician would examine his prescriptions at the end of a month he probably would be surprised to find what a small list of drugs he had made use of altogether. But to the fact that each practitioner has his own favorites, which in no case will exactly coincide with his neighbor's list, is due the enormous number of drugs which crowd the shelves of the apothecary. If, by a judicious system of elimination, two-thirds of these could be made to disappear, it is probable that, after we had accustomed ourselves to a proper use of the remainder, no one but the manufacturers would suffer.

The tendency of modern civilization is to surround men with a constantly increasing number of objects which are at first luxuries, and then, as their use becomes universal, finally come to be regarded as necessities. But for the soldier in war the process is reversed, and he is quickly and rudely stripped to the elemental necessities. The more active the campaign, the more does the great basic problem of transportation assert itself, and the more severe is the process of elimination of superfluities, and when the trains at last carry only food and ammunition, these, with his rifle, his blanket and the clothes on his back, constitute the soldier's irreducible minimum of equipment and supply. The medical department, like every other part of an army, must come under the inexorable restrictions of the question of transportation, and on the redundant superfluities of the pharmacopeia this process of elimination must fall with a heavy hand.

The military surgeon should be accustomed, even in time of peace, to work with a few tools and to get full use of them, and so in all military establishments he is required to adapt himself to the use of the standard therapeutic agents and to a supply table in which duplicates in therapeutic effect are as far as possible eliminated. But to the civil practitioner who comes into the military service and encounters the narrow limitations of field service, without any preparatory training, the bald economy of a list in which half of his pets do not find a place, is faced with rebellion and disgust, and the lack of the corner drug store is very acutely felt. The weaning period is apt to be one of wails and complaints against a niggardly government and a moss-backed and hide-bound medical department, but time and experience do not fail to bring to the medical recruit the silence of philosophical contentment.

The first medical supply table for our Army known to the writer was published in the Army Regulations of 1814. It contains 103 drugs, including different preparations of the same medicinal agent. The unsuitableness of fluid preparations for military use had even then become recognized, and the list contains no tinctures, the only fluids being acids, oils and four spirits. About half the list are still represented in one form or another in the present supply table. Many have so long disappeared from modern medical practice that their names are unfamiliar to the physician of to-day, such as gamboge, lapis culaminaris, folia supul. communis, radix scicent. virg. (?), spermaceti and oleum succini.

The simplicity of the regimental hospital in the field can be judged from the transportation allowed it in the following regulation:

"4. A two-horse wagon shall be allowed to each regimental hospital, in which shall be conveyed a medicine chest of 200 or 300 weight, and three other chests under lock and key for blankets and bed sacks, cooking utensils and hospital stores."

A faint adumbration of the female nurse in the Army is to be found in these regulations, but the duties of this humble prototype would be scorned by her proud and accomplished sisters of to-day and in this more gallant age are relegated to the hospital orderlies. Regulation 3 provides that—

"3. Every regimental hospital shall be supplied with one or more female attendants. It shall be the business of these to scour and cleanse the bunks and floors of the rooms or tents, to wash the blankets, bed sacks and clothes of the patients, to cook the victuals of the sick and to keep clean and in good order the cooking utensils."

It is interesting to examine the supply table of the United States Army, published in 1863, after two years of experience in a great war, and to compare it with the supply table of forty years later. The list of 1863 contained 130 drugs, of which 6 are different preparations of the same drug. Of these, 100 are found in substantially the same form among the 206 drugs on the supply table of to-day. Among those which have been dropped out the most notable are catechu, chlorinium (materials for preparing), conium, potas, nitras, scylla pulvis, senega, spigelia, valerian, veratrum viride and zinc acetas, carbonas and chloridi liquor. A reminder of the days of hospital gangrene and laudable pus is contained in the directions for preparing chlorin gas, and it is directed that the gas be generated under every alternate bed every night when the wards contain many sloughing wounds or are subject to epidemic disease or low fevers. One noticeable feature of the list is that it is probably the only supply table ever published for the Army in which calomel and tartar emetic are omitted. Their omission is explained by the following circular:

[Circular No. 6.]

SURGEON-GENERAL'S OFFICE,
WASHINGTON, D. C., May 4, 1863.

1. From the reports of medical inspectors and the sanitary reports to this office, it appears that the administration of calomel has so frequently been pushed to excess by military surgeons as to call for prompt steps by this office to correct this abuse; an abuse the melancholy effects of which, as officially reported, have exhibited themselves not only in innumerable cases of profuse salivation, but in the not infrequent occurrence of mercurial gangrene.

It seeming impossible in any other manner to properly restrict the use of this powerful agent, it is directed that it be struck from the supply table, and that no further requisitions for this medicine be approved by medical directors. This is done with the more confidence as modern pathology has proved the impropriety of the use of mercury in very many of those diseases in which it was formerly unfailingly administered.

2. The records of this office having conclusively proved that diseases prevalent in the Army may be treated as efficiently without tartar emetic as therewith, and the fact of its remaining on the supply table being a tacit invitation to its use, tartar emetic is also struck from the supply table of the Army.

No doubt can exist that more harm has resulted from the misuse of both these agents, in the treatment of disease, than benefit from their proper administration.

W. A. HAMMOND, Surgeon General.

But it was said that the heavy hand of the patriotic practitioner could not be thus arbitrarily restrained,

THE SYMPTOMS AND DIAGNOSIS OF OBSTRUCTION OF THE MESENTERIC VESSELS.

The diagnosis of intraabdominal disease is at times admittedly difficult. Nevertheless, the symptoms, apart from an accurate diagnosis, are not rarely sufficient to justify surgical intervention, which may thus be the means of saving life under desperate circumstances, while, even if it prove to have been unnecessary, little additional risk will have been incurred.

Among the obscure and uncommon disorders of the abdominal cavity is occlusion of the mesenteric vessels, which gives rise to a train of symptoms at times strongly suggestive of intestinal obstruction, and for the relief of which the sole hope resides in abdominal section and removal of the gangrenous bowel. This subject is exhaustively treated in the article commenced in The Journal this week by Drs. Jackson, Porter and Quimby.

Among other American authors Roswell Park[1] has recently reported two cases of this condition, both of which terminated fatally, despite prompt operation, and he considers at some length the etiologic factors and the symptomatology, and briefly the treatment. As he points out, the mesenteric veins are unprovided with valves and the arteries are terminal, so that in the event of obstruction to the flow of blood through these vessels from any cause the establishment of a collateral circulation is ordinarily not to be expected. Such obstruction may occur as a result of embolism secondary to mitral stenosis or arteriosclerosis, or of thrombosis secondary to a similar condition in the veins of the pelvis, the kidneys or the intestine. The interference with the circulation is followed by necrosis and infarction varying in extent with the vascular area involved, and in accordance with which also the mode of onset and the intensity of the symptoms vary. In the most severe cases the patients indicate almost the exact moment when the pain sets in, the remaining symptoms following in quick succession. The pain is at times paroxysmal, at other times continuous. It is almost always severe and often agonizing. It is sometimes described as intense colic. Rarely it is slight or absent. Diarrhea occurs in from 30 to 40 per cent. of the cases and is usually an early symptom, the discharges being profuse and bloody. The symptoms of intestinal obstruction at times resemble those of ileus, at other times those of constipation, and they may be followed by diarrhea. Vomiting usually occurs early, the matters ejected being bloody, or even fecal. The pulse is rapid, rarely being under 110, and it may reach 130 or 140. The temperature is at times subnormal. Meteorism appears early and becomes marked. Together with abdominal rigidity, it renders examination difficult, although both indicate the gravity of the situation, while they interfere with the means for affording relief. At a later period fluid may find its way into the peritoneal cavity, and finally symptoms of collapse and delirium make their appearance and are followed by death. It is said that tenesmus, sacral pain and the presence of fresh blood in the stools are indicative of obstruction of the inferior mesenteric artery, and that pain in the umbilical region and tea-ground stools point to obstruction of the superior mesenteric artery. It is scarcely possible to make a distinction between occlusion of the artery and that of the vein. In every instance in which the existence of mesenteric thrombosis or embolism is suspected search should be made for the presence of a similar lesion elsewhere.

Among the conditions from which mesenteric thrombosis and embolism are to be differentiated are perforating ulcer of the stomach and the duodenum, phlegmonous gastritis, abscess of the stomach, acute intestinal obstruction, pancreatitis, acute splenic infarction, acute appendicitis, acute cholecystitis, ruptured ectopic pregnancy and various intrathoracic disorders, such as pneumonia. The treatment consists in opening the abdominal cavity and resecting the gangrenous bowel.

EPIDEMIC CEREBROSPINAL MENINGITIS.

The specific type of cerebrospinal meningitis which is now generally conceded to be due to the meningococcus of Weichselbaum is endemic in many of the cities of this country and in certain eastern cities has assumed epidemic form. The statistics of Greater New York show that, while last year the average number of deaths from the disease in the springtime was about six per week during the present spring the deaths have averaged over sixty per week. The death rate of reported cases seems to be near to 50 per cent., which is about what is usual in ordinary epidemics.

The most interesting feature of the present epidemic is the inevitably suggested relationship between epidemic cerebrospinal meningitis and croupous pneumonia. Foreign clinicians are practically a unit in declaring that the disease is likely to be more frequent at periods when pneumonia rages with special virulence and that, on the other hand, pneumonia itself is likely to be complicated by meningeal symptoms much more frequently when specific cerebrospinal meningitis is epidemic. Pneumonia has been more prevalent and more fatal this year than ever before, and so the announcement of epidemic cerebrospinal meningitis raging with virulence is an exemplification of the old observation that has so long had a place in the text-books. Just what possible connection there may be between the two diseases is as yet undetermined. It is to be hoped that the present epidemic will furnish opportunities for the successful solution of this important problem. There are many bacteriologists who seem to think that just as the pneumococcus may exist in a healthy throat without producing any bad effect until certain conditions arise to give it the chance for successful invasion of the lungs so the meningococcus intracellularis may exist in the secretions of a healthy nose until a favorable combination of circumstances gives it the opportunity for an invasion of the meninges. The meteorologic conditions favoring the two diseases seem to be the same

---

[1] Annals of Surgery, April, 1904, p. 554.

As to whether the disease is contagious or not also remains unsettled. Certain it is that the affection does not seem to be traceable from person to person who have been in contact with patients suffering from the disease, but occurs in many parts of the city at about the same time and without any recognizable relation to preceding cases. It has been said that the disease occurs more commonly in crowded, uncleanly populations. This, however, remains to be demonstrated, since the superabundance of population in such quarters justifies the occurrence of more cases of the disease on simple numerical grounds without any necessity for pleading a greater predisposition to its acquirement.

The treatment of the affection so far has not been satisfactory. In cases of sudden onset, where the prognosis is grave, and where coma comes early in the case, the removal of a certain amount of cerebrospinal fluid by lumbar puncture often brings relief of symptoms and the apparent beginning of a decided movement toward recovery. At times where there is a relapse into coma, or even a series of them, further relief may be afforded by the lessening of intracranial and intraspinal pressure by successive withdrawals of cerebrospinal fluid. The question of injecting some mild antiseptic that might prove effective in helping the tissues to get rid of the infective agent occurs at once. A 1 per cent. solution of lysol has been used for this purpose with apparent relief in some cases, though there are conservative observers who do not consider that it affects the eventual course of the case. Epidemic cerebrospinal meningitis is in its course so uncertain a disease that it would require an analysis of a large number of cases treated in this way before a definite decision could be reached. In the meantime all are agreed that opium must be used freely to relieve the patient from the intense discomfort accompanying the disease, and by making him less restless give better chance for the avoidance of the exhaustive condition which surely facilitates a fatal termination.

EMPIRICAL METHODS IN THE TREATMENT OF INOPERABLE CANCER.

In the cancer wards of the Middlesex Hospital are only cases of inoperable disease, and it has been the policy of the medical office to give these patients the benefit of a trial of the various "cures" that are suggested from various sources from time to time, whether the cure is based on rational grounds or not, provided always that the trial is not prejudicial to the comfort or the health of the patient. In the recently issued report from this hospital the results of these therapeutic experiments are given, and, although they are about what might be expected, yet a perusal of the report is extremely interesting. Some of the methods employed are noticeably much more under consideration in England than here, as, for example, the operation of oöphorectomy for carcinoma of the breast. This method was introduced by Beatson, on the principle that the atrophy or removal of the ovaries is followed by atrophy of the breast, and that possibly similar changes might occur in the cancers of this organ. The impression that seems to have been gained by the experience of the hospital and of operators elsewhere in England is that in some cases oöphorectomy has been followed by decrease in size of the original growths, and particularly of recurrent nodules about the scar left after operations on the breast. The best results have been obtained in patients over 40 and before the menopause, and when they are free from bone and visceral complication. However, the cases reported from the Middlesex Hospital would hardly suffice to arouse much enthusiasm over the benefits of oöphorectomy, and some of the English surgeons even take the ground that this procedure really augments the rate of growth of the tumors.

Treatment with electric currents of high potential and rapid frequency has also attracted attention, particularly because of a general popular interest aroused by the press. Beyond some improvement in the general tone of the patients and slight changes in the local conditions, no results were obtained. The lay press also stirred up much enthusiasm over a most simple way of "curing cancer," in which the potent agent was an extract of violet leaves; reports of definite cure were not wanting. Even this remedy was given a fair trial—with no results, of course. Marigold ointment was another vaunted specific which failed to live up to its reputation. One of the latest of these empirical methods is of Australian origin, the *vis medicatrix* being furnished by molasses. Our English confrère had some difficulty in procuring this material and eventually had to get it from Louisiana. Even with this, the real article, no cures were obtained; possibly, however, there is a difference in the therapeutic worth of the Louisiana and the Australian products! Of ordinary drugs the only ones tried were Chian turpentine and anilin chlorid, both of which have had "booms."

Cancroin, which was introduced by Professor Adamkiewicz of Vienna, has caused much spirited controversy on the continent, although little heard of here. Originally the "poisonous products of cancer tissue" were used, but now neurin is used in their place, and remarkable results have been described by certain Viennese physicians, and warmly questioned by others. In the Middlesex cancroin seems to have succeeded chiefly in causing much pain when injected, without any beneficial results. Acting on the hypothesis advanced by Foulerton, that the secretion of the thyroid and thymus exerted an inhibitory effect on the growth of epithelium, a number of cases were treated by extracts of these organs and also with serum from animals immunized against them; seemingly the results have been practically nothing. The *x*-rays have given by far the best results in these inoperable cases, particularly through their ability to clean up the ulcerating surfaces and to lessen pain. The effect on pain seems to be dependent on a sensory paralysis, which may also be observed in *x*-ray dermatitis, and pain due to pressure of the growth on nerve trunks is not readily influenced. Their results, however, hold out no prospects of cure in any of these advanced cases, and they state plainly that "*x*-ray treatment of malignant disease should never be attempted where an operation is possible," although it also is claimed that "in *x*-rays we have an agent that has perhaps done more for the relief of inoperable cancer than any method hitherto known." It is interesting to note that investigations have been made of the various cancer parasites that have been described in recent years, and that none of them is considered worthy of detailed notice in the laboratory reports.

ANTICROTALUS VENIN.

A number of years ago Calmette succeeded in preparing an anticobra venin that has decided protective properties against cobra venom, but it has been shown that this antivenin does not protect against the venom of other snakes, as, for instance, the rattlesnake (*Crotalus adamanteus*) venom. This is not surprising, however, because we know through the researches of Flexner and Noguchi that the venoms from different species of snakes have a very different constitution. Cobra venom owes its toxicity chiefly to neurotoxin and rattlesnake venom to hemorrhagin which destroys the endothelial cells lining the small blood vessels and causes extravasation of blood into the tissues around the point of inoculation. These venoms contain, however, other toxins beside those mentioned, such as hemolysin, and the rattlesnake venom seems to contain still other substances having a local destructive effect on the tissues.

A number of attempts have been made to prepare an antitoxin for rattlesnake venom, but the destructive local effects of this venom were for a long time seemingly insuperable difficulties. It was clear that the local action of this substance had to be destroyed by converting the toxins into toxoids before they could be successfully used in immunization, but the great difficulty was the production of such toxoids. Heating the venom was tried, but it was found that by this treatment the hemorrhagin is entirely destroyed instead of being converted into toxoid, and hence the injection of venom thus altered does not give rise to antihemorrhagin, while it may give rise to antineurotoxin and antihemolysin because the neurotoxin and the hemolysin are not destroyed by heating to 75 C. This is the plan adopted in the preparation of Calmette's antivenin, but it leaves out of account the local effects of certain viper venoms. These local effects are, however, the chief dangers of the poisoning by rattlesnake venom, and hence any antivenin that leaves them out of account must fail to protect against this venom.

Flexner and Noguchi[1] have recently succeeded in preparing an efficient anticrotalus venin by repeatedly injecting rabbits and dogs with a solution of the venom which had been treated for twenty-four hours with 2 per cent. of HCl or .3 per cent. of ICl_3. Crotalus venom thus treated is deprived of its destructive local effects, but when injected into an animal is still capable of producing antibodies for the locally acting substances. Evidently the HCl and the ICl_3 convert the hemorrhagin, and probably other toxins contained in the venom, into toxoid; 0.5 c.c. of serum thus prepared by injecting a rabbit protected white rats against several times the minimum fatal dose of rattlesnake venom, while it failed to exhibit any antitoxic effect for cobra and daboia venom. This serum is markedly antitoxic and antihemorrhagic for crotalus venom, but not antihemolytic or antineurotoxic, because the HCl and the ICl_3 entirely destroy the hemolysin and neurotoxin instead of converting them into toxoids. The neurotoxin and hemolysin are not important constituents of the rattlesnake venom, and hence they may be left out of account in the production of antivenin for this particular venom. It is different, however, with the cobra venom, because here the neurotoxin is the most important constituent, and we could therefore not expect that anticrotalus venin would protect against cobra venom. The experiments have brought to light the interesting fact that anticrotalus venin does not only fail to protect against cobra and daboia venom, but it hastens death of the animals when injected with these venoms. It will be interesting to know why this serum accelerates death by the other venoms, but this point has not yet been positively determined.

INJECTION OF ADRENALIN TO PREVENT REACCUMULATION OF SEROUS EFFUSIONS.

Effusion of fluid takes place into serous cavities under a variety of conditions, principally inflammatory and cardiovascular. When present in small amount, the fluid may, and it usually does, undergo spontaneous absorption. If, however, the amount be large, not only may the fluid remain unabsorbed, but it may, beside, be a source of distinct danger by reason of the pressure it exerts on vital organs, with the resulting interference with function. To secure relief under the latter conditions, puncture or aspiration or some form of resection often becomes necessary, but even then the fluid may reaccumulate, at times with great rapidity, so that repeated operation is required. It would be a decided advantage to possess a means by which such a difficulty could be obviated, and the suggestion has recently been made on the basis of clinical experience that reaccumulation of fluid in serous cavities after aspiration can be prevented by injection of adrenalin chlorid.

---

[1] Jour. Medical Research, May, 1904.

Having observed in a case of abdominal carcinoma with secondary involvement of the pleura that the injection of one dram of 1-1000 solution of adrenalin chlorid, after removal of a large amount of fluid that had repeatedly accumulated in the pleural cavity, was followed by failure of further accumulation, Dr. James Barr[1] was led to employ the same expedient in a case of ascites secondary to cirrhosis of the liver, in a case of pericarditis with effusion subsequently complicated by pleurisy with effusion first on the left and then on the right side, in a case of tuberculous peritonitis with ascites, and in another case of pleurisy probably tuberculous with effusion, with equally satisfactory results in all. In the last three cases from one-half pint to three pints of sterilized air was additionally injected after removal of the fluid in the hope of preventing adhesions. The injected air may serve, beside, as a means of preventing possibly fatal collateral hyperemia and edema of the healthy lung in consequence of the diminution in pressure resulting from the withdrawal of a large amount of fluid from the pleural cavity. The air is absorbed slowly, and for this reason it is to be preferred to oxygen. Under certain circumstances, however, as when an excessive number of leucocytes are present in the fluid or there is an apparently commencing formation of pus, it is thought the injection of hydrogen dioxid might be of advantage. A special form of apparatus, serving at once as siphon, syringe and aspirator, was devised for removing the fluid and injecting the adrenalin solution and the sterile air. Under all circumstances great care must be exercised in the manipulations in order to avoid accidental infection. In an additional case of hydrops ventriculi, supposed to be due to a cerebellar tumor, ten minims of adrenalin solution were injected twice and twenty minims once after removal of several ounces of fluid from the lateral ventricle and drainage.

While the number of observations recorded is insufficient to permit of the formulation of definitive conclusions, they may serve as the starting point for further clinical trial. It seems superfluous to add in this connection that, like other agents having great physiologic activity, adrenalin must be employed here, as elsewhere, with great discrimination.

RACE SUICIDE.

The *Chicago Inter Ocean* points out the well-known fact that, with the imperfections of the vital statistics in this country, we can form very little idea as to the increase or decrease of the birth rate. But abroad, where special records have been kept most accurately for years, the case is somewhat different, and the question of race suicide can there be put to the test of fact. It quotes from the recent volume of H. G. Wells, "Mankind in the Making," which applies this test to England and Wales, and finds that, while the birth rate has declined between 1850 and 1896 from 33.8 to 28 per 1,000, the death rate has also declined from 23.3 to 17.7. Subtracting the death rates from the birth rates leaves a normal increase of the population and shows only a fall of 0.2 per 1,000. But he still further shows that the ratio of illegitimate births has declined in England and Wales from 2.2 in the period from 1846 to 1850 to 1.2 in the period from 1896 to 1900, and that but for this decrease an actual rise of 0.8 per 1,000 would have been shown by the figures. This would indicate that England and Wales are not only not becoming decadent by the decreasing birth rate, but are becoming more moral, and in this counteract the deficiency of 0.2 per 1,000. The fact is that the question of race suicide is really a local one. It may be a serious fact in certain sections, but applied to large territories or whole countries there are many factors which have to be considered, and which will necessarily call for much reserve in any conclusions that may be deduced.

ANGINA PECTORIS AND ABDOMINIS.

While many cases of angina pectoris are attended with sclerosis of the coronary arteries, the latter condition is not rarely encountered independently of symptoms of the former. It would thus appear that some other factor must be responsible for the clinical picture, and existing evidence supports the view that this resides in increased vascular tension. Symptoms of angina pectoris have been observed also in association with obvious vasomotor phenomena in the extremities, without demonstrable disease of the heart. Dr. J. Pal,[1] as a result of clinical studies, considers the phenomena in the peripheral vessels as an integral part of the attack of true angina, which he includes among the vascular crises. He recognizes two typical varieties, namely, the pectoral and the abdominal. The latter is comparable, in his opinion, with the abdominal crises of tabetic patients and with lead-colic, the symptoms of which he attributes to contraction of the abdominal vessels. It is a well-recognized fact, further, that sclerosis or occlusion of the abdominal vessels is attended with pain of varying severity and duration, often associated with symptoms suggestive of intestinal obstruction. Pal has observed a number of cases of both pectoral and abdominal angina in which during the paroxysm, the pulse-tension was found increased both by palpation and by tonometric estimation. The nutrition and the function of the heart will necessarily suffer, and death may take place as a result of the disease of the coronary arteries; but this condition is not sufficient to account for the attacks of angina. General increase in arterial tension is not alone the determining factor in an attack of angina, but this consists rather in the limitation of the vascular constriction to circumscribed areas, as, for example, the thoracic or abdominal viscera, and this may be brought about as a result of reflex influences. Therapeutically, good results have been obtained from the use of nitrites and iodids, while more recently the administration of preparations of theobromin and of cyanids has been recommended. Morphin relieves the pain of the attack, without influencing the arterial tension, and it may thus fail to avert a fatal issue.

CLINICAL OBSERVATIONS AND MECHANICAL REFINEMENT.

An interesting subject considered at the recent meeting of the Association of American Physicians was that presented by Stengel[1] on "Clinical Studies in Arteriosclerosis." According to Stengel's observations the first sign of beginning arteriosclerosis, which occurs at a considerable period before any thickening of the artery can be observed, is a prolongation of the first sound of the heart. With care this can be observed before the accentuation of the second sound. As it is at this period of the affection that prophylactic measures may be of real help, this observation would seem to be of the first importance for the treatment of a disease which so far has been considered rather out of the range of successful therapeutics. Another of the very interesting observations made is that in spite of the general impression to that effect, blood pressure in arteriosclerosis is not necessarily always high. The observations demonstrating this point were made with a Riva-Rocci sphygmomanometer, as modified by Stanton in this country. This instrument measures not only the blood pressure during systole, but also and especially during diastole. Stengel's results obtained in this matter were confirmed by a manometer applied to a peripheral artery. Constant high blood pressure during diastole is indeed an invariable characteristic of arteriosclerosis. In the discussion Cohen pointed out that years ago Sir William Broadbent had emphasized the fact that in the early stages of arteriosclerosis, as also, of course, later in the affection, pulse tension remained high always between the pulse beats, that is, during the diastole of the heart. Broadbent's observation then, made with the unaided finger and now confirmed by means of a very delicate and rather complicated instrument, shows that some of the old trained delicacy of observation could accomplish as much, with less waste of time, as is now accomplished by means of intricate mechanical appliances.

THE SPECIFICITY OF THE TYPHOID BACILLUS.

Although at the present time we are generally ready to accept without question the idea that the typhoid bacillus is the sole cause of typhoid fever, because of the enormous amount of evidence of various sorts that has accumulated pointing to this view, yet there has always been one weak point in the evidence. The first two of the postulates of Koch that should be fulfilled by an organism before it can be fully accepted as the cause of a given disease have been abundantly satisfied, namely, that the organism must be found constantly present in the disease, and that it must be recovered in pure cultures from the diseased tissues. The third requirement, that the germ produce in an experimental animal the same lesions as are characteristic for the disease in man, has been the stumbling block. Inoculation into animals usually results in the development of acute degenerative changes in the organs, with often much swelling of the lymph glands, and sometimes of the intestinal follicles, but these changes can be produced to a considerable degree by other organisms, and it can hardly be said that the characteristics of typhoid as we see it in man have been reproduced in the experiments. On the other hand, the features of the lesions are quite similar to the anatomic changes found in man, lacking chiefly the characteristic enlargement and ulceration of Peyer's patches. By utilizing the chimpanzee, however, Grunbaum[1] has been more successful, probably because of the closer anatomic resemblance of the lymphatic apparatus of this animal to that of man. In each of two chimpanzees to which were fed typhoid cultures, quite characteristic changes were found in the intestines at autopsy twelve days after the bacilli were administered; the blood also gave the Widal reaction in dilutions of 1-80. The animals did not seem to become very sick, and two animals that were also given typhoid bacilli, and not killed, as were those that were autopsied, did not suffer severely from the infection. Such experiments as these are of great value, but are, of course, almost prohibited by the rarity and cost of chimpanzees. Although it was not necessary to have these results for the purpose of establishing the importance of the bacillus of Eberth, yet it is gratifying to have the last gap in the chain filled. For practical demonstration of the specificity of this bacillus, the recent case of a French woman who attempted suicide by swallowing a culture obtained in a laboratory, is fully as convincing. However, although she developed unquestionably a true typhoid fever, as she recovered it is, of course, impossible to say that she did develop the ulcers in Peyer's patches and the other characteristics of the disease.

THE COLLEGE WOMAN AND CHILDREN.

An interesting article on childbearing among college-bred women is contributed to a current magazine[2] by one who claims to be a college woman herself and intimately acquainted with the views of college women and with their conditions. Recent discussions with regard to the decreasing number of children in native American families has brought out the fact that the group of college graduates has a lower birth rate in proportion to number than any other selected group of women. Statistics in Massachusetts, at least, seem to show that the average number of children of a college-educated wife is less than two; to be exact, just 1.8 children on the average are born to each such mother. As a large proportion of college women—in the eastern states considerably more than 50 per cent.—do not marry, it is easy to understand that the race of college women would soon die out unless supplied by accessions from other social strata. The writer of the article referred to gives a vivid account of some personal knowledge as to the reasons for this low birth rate. They may all be summed up in two, actual infertility and the great danger involved in childbearing for women evidently not intended by Nature to be mothers. She thinks that the real reason for the smallness of the college woman's family is not that they will not, but because they can not, have children, and she tells the story of the experience of various of her classmates. The writer goes so far as to assert that, to her personal knowledge, many women who are prominent in quasi-public life are really desirous of children, but they know that they can not have them or that their having them would entail so much risk of life that child-bearing is out of the question. To the ordinary family physician these claims will doubtless seem exaggerated. There are weak, delicate women, incapable of child-bearing, but this is surely not generally true. At the present time the athletic woman is more than ever in evidence, and the physical development of the American girl—the main element of which is composed of college women—is the admiration of the world. On the other hand, it is admitted that conditions of incomplete development of the genital organs in women are much more frequent than used to be the case. It would seem as though the intense mental application so freely encouraged by our modern educational system during the precious years between twelve and sixteen, when the maid stands where the brook of girlhood and the river of womanhood meet, may very well serve to divert Nature's purpose of developing the sexual side of the being. Even though not so many cases of lack of family or small families are attributable to this fact, as this writer claims, it still behooves physicians to raise their voice in protest once more against the unnatural conditions that have developed and are unfortunately developing still more in our present-day educational system.

THE EPIDEMIOLOGY OF DYSENTERY.

The zealous investigation of the varieties of dysentery bacilli and their agglutination reactions has not been altogether paralleled by epidemiologic studies, and there still remain many obscure points in the etiology of dysentery as affecting both infants and adults. Any inquiry that tends to throw light on modes and sources of infection is, therefore, likely to be welcomed with especial interest. Conradi[1] has recently made an investigation into the prevalence of dysentery in the neighborhood of Metz, and is led by his findings to ascribe the recent extension of the disease in that region to contact infection. There are reasons for believing that in certain districts in Lothringen, especially around Metz, the embers of the disease have been smouldering since the Franco-Prussian war. The recent flaming up of dysentery in this quarter is apparently due, in part at least, to the growth of a non-immune generation, since it appears from the facts adduced by this author that in the recent epidemic the indigenous population of twenty-five years and upward has remained practically exempt from infection. This relative immunity of the older generation is accounted for on the ground of the very general infection of the population in 1870. The author's arguments in favor of the spread of the disease by contact are such as to carry conviction, and are very similar in character to those that have recently been very generally urged for the similar view of causation of typhoid fever. In dysentery, as in typhoid fever, the mild and the chronic cases are believed to be the particularly active agents of dissemination. The dysentery bacillus, to an even greater degree perhaps than the typhoid bacillus, does not seem to maintain its vitality long outside of the human body, and the disease is very largely kept alive by a more or less direct transfer from case to case. There is perhaps nothing particularly novel about all this, although it may be admitted that the situation at the present time warrants special emphasis being laid on the danger incurred by the community in allowing the specificity of mild cases of intestinal infection to pass unrecognized, and the patients themselves to roam at large without control or supervision. The well-known facts concerning the spread of both dysentery and typhoid fever through military encampments afford strong proof of the serious character of contact infection. The full realization of the possibilities in this quarter, although hardly a new discovery, is of sufficient importance to justify all the stress that can be placed on it, and the German investigators who are following Koch's lead in this matter are aiming at a real evil, although perhaps with more of the flourish of discoverers than the historic sense would seem to countenance.

THE RELATION BETWEEN PULMONARY AND LARYNGEAL TUBERCULOSIS.

The intimate relation which exists between pulmonary and laryngeal tuberculosis has only been appreciated by the physicians of the last generation. Nearly all of the writers up to 1880 were of the opinion that the majority of the laryngeal complications of consumption were not due to the same cause as the pulmonary lesion. Even at the present time there are great discrepancies in the statistics bearing on the relation between the two conditions. Recently, Frese[1] has analyzed a large number of cases of pulmonary tuberculosis with regard to the laryngeal complications. He finds that primary laryngeal tuberculosis is extremely rare, as has been always held. He believes this due to the great difficulty of lodgment of tubercle bacilli on the larynx from the filtering action of the nose and the action of the ciliated epithelium. In practically all cases the laryngeal lesion follows the pulmonary one, the larynx being secondarily affected only less frequently than the intestinal tract. In Frese's series of four hundred and fifteen cases of phthisis laryngeal tuberculosis was present, he says, in ninety-three, or about 23.5 per cent. Most cases occurred between the ages of twenty and thirty, though no age was absolutely immune. Contrary to the general opinion, women were attacked as frequently as men; in fact, slightly more frequently according to Frese's figures. The most interesting question in these cases is the method of infection. Is the infection of the larynx due to direct infection from the sputum, or are the tubercle bacilli deposited by the lymph or blood channels? The supporters of transmission from the lung by the blood or lymph claim that at times the laryngeal lesions are unilateral, and situated on the same side as a unilateral lung lesion, or if both lungs are infected, on the side most markedly diseased. Frese's experience does not support this view. He found that sometimes the lung lesion is on one side and the laryngeal lesion on the other, and he also calls attention to the great difficulty in bilateral lung lesions of estimating which side is most affected. Another fact often cited in favor of blood or lymph invasion is the fact that the laryngeal lesions generally begin beneath the mucosa and not on it. Frese shows by experimental lesions on dogs that where the lesion is due to direct inoculation of tuberculous material on the mucosa, this is also the case. He concludes from these experiments and from his clinical experience that the involvement is due to direct implantation of tubercle bacilli from the infected sputum. The reason why this occurs in the larynx and not in the trachea or larger bronchi is an anatomic one. The shape of the larynx renders it an easy lodging place for sputum, and, in fact, the author states that in examining his cases sputum was often to be seen lodged on the larynx. The non-involvement of the larynx in many cases is due, he thinks, to the great variation in the amount of sputum in different cases, the differences in the number of live bacilli which are found therein, and differences in individual resistance. Where the laryngeal involvement is severe, its effect on the lung lesion is usually bad, the interference with swallowing, the stenosis of the air passages, and the increased chances for aspiration of infective material, all lead, in most instances, to a rapidly fatal termination of the case.

OBJECTIONABLE MEDICAL ADVERTISEMENTS TO BE EXCLUDED FROM THE MAILS.

In another column will be found a note in regard to the proposed movement of the Postoffice Department for the exclusion of objectionable matter from the mails. This means the exclusion of obscene advertisements and all advertisements which misrepresent, or which defraud and deceive the reader. If this is carried out it will be a long step in advance toward purifying current American newspaper advertising literature. The law, which we quote, certainly warrants this action of the postoffice authorities. It is said, moreover, that the movement has the endorsement of the American Newspaper Publishers' Association, and it goes without saying that moralists as well as medical men and other scientists will endorse it most thoroughly. Some opposition may be looked for from certain quarters, but no reasonable objection can be raised against the proposition. This action of the postoffice authorities will also generalize the law which already exists in one or two states, notably in Michigan, against such advertisements. The postoffice is a national affair and has control of the mails. It will be seen that there are severe penalties against such offenses as are noted; in fact, it amounts to a national law against indecent advertising and applies to the whole country without regard to state boundaries. The offense will come before the United States courts, which is also a satisfactory consideration. We hope that its enforcement will be begun immediately and a source of demoralization that now is altogether too general be done away with. A few years ago a Chicago newspaper publisher came under this rule. His offense was an aggravated one, however, and a precedent was not recognized as set for the lesser offenders who were not so glaring in their iniquity. It is unfortunate that Uncle Sam's postal arm does not reach over other means of distributing these fraudulent advertisements than through the mails, but yet this one agency will go a long way toward checking the evil.

Medical News.

DISTRICT OF COLUMBIA.

Columbian Commencement.—On May 25 a class of 52 was graduated from the medical department of Columbian University.

Health of the District.—The report of the health officer for the week ended May 21, shows the total number of deaths to have been 120, and the total number of births 122. At the close of the week there were under treatment 11 cases of diphtheria, 26 of scarlet fever, 56 of typhoid fever and 6 of smallpox.

Large Libel Verdict.—Arthur MacDonald has been granted $20,000 damages against the *New York Sun* for libel and defamation of character. Mr. MacDonald was formerly connected with the Bureau of Education at Washington, dealing and writing principally on the study of children, criminology and socio-pathologic subjects.

ILLINOIS.

Medical Student Dies.—Jesse G. Strobridge, Harvard, a junior in Rush Medical College, died recently in San Diego, Cal., where he had gone in the hope of regaining health.

Langdon Remanded.—Dr. Peter R. Langdon, Kankakee, now under arrest in London on the charge of performing an illegal operation, has been remanded for one week, pending instructions from the Secretary of State.

Personal.—Dr. John A. Pratt, Aurora, will leave for Europe in a few weeks.——Dr. Eugene G. Simpson has been appointed health officer of Naperville.——Dr. Peter S. Weidman, Edwardsville, who retired in 1899, has decided to re-enter practice.——Dr. Marvel Thomas, Gillespie, has retired from practice.

Chicago.

Chicago Dumping-Ground for Smallpox.—On May 25 a patient with confluent smallpox, who had been sent from Wisconsin, walked into the health office.

Church Gives Tent for Consumptives.—Central Church has devoted the collection of one Sunday to the providing of one home-tent for consumptives at White Head, Colo.

Gives to Catholic Charities.—The late Thomas Brenan, in his will, devised $1,000 each to St. Joseph's Hospital, St. Elizabeth's Hospital, Mercy Hospital, and Alexian Brothers' Hospital.

A Healthy May.—The May mortality of Chicago was the lowest on record, the death-rate was only 13.44 per 1,000 per annum. The average rate for the preceding decade was 15.63 per 1,000, showing a reduction of about 14 per cent.

Unvaccinated Have Smallpox.—The department of health calls attention to the fact that of the 82 cases discovered in Chicago since the first of the year, the most searching examination has failed to find a single one who had been properly or recently vaccinated.

Death Causes.—For the week ended May 28, 437 deaths were recorded, equivalent to an annual death rate of 11.82 per 1,000. Pneumonia caused 55 deaths, or about 12.6 per cent.; consumption, 48; heart disease, 37; Bright's disease, 32; acute intestinal diseases, 29, and violence, 26.

State Board Prosecutions.—The State Board of Health has prosecuted Ottoman, etc., Hanish, charged with violating the medical practice act by the use of "torture" needles and "lotus-oil" injections.——A warrant has been secured by the State Board of Health for the arrest of "Dr." August Van Bysterveldt, charged with practicing medicine without a license.

Personal.—Dr. George W. Webster has been appointed by the governor as a delegate to the National Conference of Charities and Corrections to be held in Portland, Maine, June 15 to 22.——Dr. Rudolph Menn has been appointed to fill the vacancy in the surgical staff of Cook County Hospital caused by the death of Dr. Edward H. Lee.——Dr. Joseph Z. Bergeron sailed for Europe, May 31.

MAINE.

Gift to Hospital.—Knox County General Hospital, Rockland, has received a gift of $1,000 from Messrs. Francis and George W. Smith of Warrenton.

Personal.—Dr. and Mrs. John G. Gehring, Bethel, have sailed for Europe.——Drs. Daniel W. Wentworth. Sanford, and Byron M. Moulton, Springvale, have been appointed physicians by the selectmen of Sanford.

Holy Ghoster in More Trouble.—"Rev." Frank W. Sandford, who is now under conviction of cruelty to his son, but is out on appeal, has been further tried and found guilty of manslaughter in causing the death of a 14-year-old boy, by neglect. Sandford is the head of the Holy Ghost and Us Society in Shiloh, Me., claims to be "The Holy Ghost," and exercises absolute authority of life and death in his colony. Many cases of extreme cruelty have been known to the people of the region and led to these trials. This boy was ill with diphtheria, had absolutely no medical treatment, but was required to fast.

MARYLAND.

Personal.—Dr. Arthur E. Sudler, Sudlersville, has been made president of the board of school examiners of Queen Anne County.

Milk Colored with Annatto.—According to the secretary of the State Board of Health, almost all the milk sold is colored with annatto, which is made in Vermont, and is used to render milk yellow. It is said to be harmless in the small quantity—a few drops—needed for this purpose. People will not buy milk unless so colored.

Baltimore.

Deaths and Smallpox.—For the week ended May 28, 194 deaths were reported, and five cases of smallpox were reported.

Toward Hospital Auxiliary.—About $12,000 of the fund necessary to build an auxiliary to the Orthopedic Hospital has been raised.

Personal.—Dr. William Osler will entertain the members of the American Association of Medical Librarians at dinner at the Traymore, Atlantic City, June 6.——Dr. William Lee Howard sails for Europe June 5.

Smallpox Gaining.—Smallpox has been steadily gaining ground. The health commissioner will appoint 25 extra vaccine physicians to assist the health wardens. They will be appointed for two months and will receive $75 each. There have been 18 cases of smallpox here since May 1, and on May 25 there were 15 cases and 15 suspects at quarantine.

Hoffa in Baltimore.—Prof. Albert Hoffa of Berlin, orthopedic surgeon, was in Baltimore, May 27 to 29, as the guest of Dr. R. Tunstall Taylor. He was accompanied by Dr. Hans Spitzy of the University of Gratz. He lectured and operated at the University of Maryland Hospital May 28. He performed a cutting and a bloodless operation for congenital dislocation of the hip, and transplanted tendons for rigid wristdrop in a young child. He is here, it is said, as a commissioner of the German government to study American surgery and orthopedic hospitals.

MASSACHUSETTS.

Hospital Advertises Need.—The Massachusetts General Hospital has made known its need of a further large endowment by the novel method of inserting an advertisement in the daily papers stating the needs of the institution and asking the attention of philanthropic friends.

Brookline Renews Mosquito Crusade.—The Brookline Board of Health has renewed its war on mosquitoes. A large force of men under the direction of the assistant bacteriologist of the town are at work petrolizing the catch-basins. Forty property owners have been notified to fill in mosquito-breeding stagnant pools and have all agreed to do so. Swamps and ponds will be covered by the town authorities themselves.

The Boston City Hospital celebrated its fortieth anniversary, May 24, by opening two new buildings, a surgical out-patient building, to accommodate surgical, genito-urinary, gynecological, throat, ear and eye clinics, and also quarters for the junior house officers in the upper story; and a building containing wards K, L and M, designed for the adequate isolation of cases of infectious diseases, such as erysipelas, cellulitis, dysentery, etc., suspicious eruptions, sunstroke cases and delirious patients. The address of Mr. Sherman, who has been chairman of the trustees for many years, showed that during these forty years the capacity of the hospital has increased four and a half times. The 6,297 patients of the first year were increased to 72,869 last year; the 8,164 out-patients to 108,280; the 203 beds to 935; the staff from 19 to 81; the house officers from 5 to 47; nurses and orderlies from 17 to 206, and the annual appropriations from $76,600 to $476,800.

NEW YORK.

Smallpox.—A number of cases of smallpox are reported from Niagara Falls.

Personal.—Dr. William W. Plummer, Buffalo, sails on a two months' cruise through Norwegian fjords.

Tuberculosis Hospital for Rochester.—The municipal hospital erected a year ago for smallpox patients, but never used for that purpose and since unoccupied, is to be given over to patients with tuberculosis. The hospital is well equipped and has accommodation for about 200 patients. It will be conducted under the direction of the health authorities.

Buffalo's Mortality.—The report for April shows an annual death-rate of 16.51 per 1,000. The principal causes of death were consumption, 45; cerebrospinal meningitis, 8; debility, 50; cancer, 24; apoplexy, 24; meningitis, 13; valvular heart disease, 26; bronchitis, 12; pneumonia, 74; appendicitis, 5; cirrhosis of liver, 5; chronic nephritis, 24; abortion, 4; puerperal septicemia, 4, and violence, 30. The total deaths were 523, as compared to 498 in April, 1903.

New York City.

Medical Officers Get Increased Rank and Pay.—The medical officers of the fire department of Greater New York have been made members of the uniformed force, with rank of battalion chief and pay of $3,000 a year.

Recreation Piers Open.—The recreation piers along the river fronts have been opened for the season. There are 17 attendants at each pier, 6 women and 11 men. A physician from the board of health is also detailed at each pier.

Emergency Tents in Parks Open.—The emergency tent stations for Van Cortlandt, Bronx and Pelham Bay parks have been opened. Victims of accidents, sunstroke, drowning, etc., will here receive first-aid. Competent men will be in charge of the tents.

Personal.—Dr. Darlington, health commissioner, is making a ten days' trip to St. Louis, Chicago and Buffalo, to study the methods of those cities in caring for public health. Chicago is said to have a cheaper method of handling refuse and Buffalo a cheaper ambulance system.——Dr. Edward T. Higgins has been appointed police surgeon at an annual salary of $3,000.

OHIO.

Railway Surgeons Elect Officers.—The Society of C., H. and D. Railway Surgeons, at its annual meeting at Dayton, May 26, elected the following officers: President, Dr. Millard F. Hussey, Sidney; vice-president, Dr. Charles E. Beardsley, Ottawa; secretary, Dr. Mark Millikin, Hamilton, and treasurer, Dr. W. E. Thesing, Cincinnati.

New Operating Building Opened.—The new operating building of the Miami Valley Hospital, Dayton, was dedicated May 26. Mrs. Frank J. Patterson, who gave the institution in memory of her husband, made the address, which was responded to by Dr. Henry F. Colby. The building and its equipment are said to be among the most modern and complete in the United States.

Personal.—Dr. and Mrs. Edward F. Cushing, Cleveland, have sailed for Europe.——Dr. Abraham S. Metzler, Baltic, 70 years of age, was assaulted at Coshocton by five men who tried to rob him, but by strength and courage he beat off his assailants.——Dr. George W. Cullen, Cincinnati, has been commissioned first lieutenant and assistant and assigned to the First Infantry.——Dr. Chester C. Kirk, Columbus, has succeeded Dr. Jeremiah H. Metzger as assistant physician at the Toledo State Hospital.——Dr. David J. Matthews, Zanesville, has been commissioned first lieutenant and assistant surgeon and assigned to Ambulance Company No. 2, Zanesville.——Dr. and Mrs. H. Wilbur Cooper, Steubenville, have returned from Europe.

Hydrophobia Scare in Gallia County.—Rumors of rabies among the dogs of Gallipolis and vicinity were confirmed May 22, when the laboratory evidences of rabies were discovered in a dog which had severely bitten a young lad. The examinations were made in the pathologic laboratory of the Ohio Hospital for Epileptics located at Gallipolis, and the positive indications of the Van Gehuchten-Nelis histologic test were confirmed by the finding of stones, straw, etc., in the dog's stomach, and by the subsequent history of the canine's actions. The injured boy was sent to the Pasteur Department of the University of Michigan for preventive treatment. As several other dogs were bitten by the rabid animal the authorities of Gallipolis fear endemic rabies, and are taking stringent precautionary measures.

Many New Doctors.—The Medical College of Ohio, Cincinnati, graduated the largest class of the year, May 25, when 46 received diplomas, 19 of whom won hospital appointments. Dr. Joseph L. Ransohoff was awarded the faculty gold medal.

Dr. Robert Bell Library.
[illegible] Medical College
32594

——Starling Medical College, Columbus, held its seventy-fifth annual commencement, May 3, and conferred diplomas on a class of 34.——Cleveland College of Physicians and Surgeons, of the Ohio Wesleyan University, awarded diplomas to a class of 18, May 4.——A class of 41 was graduated from the Ohio Medical University, Columbus, April 28.——At the twenty-third annual commencement of Toledo Medical College, 7 were given diplomas.——Miami Medical College, Cincinnati, on June 1, graduated a class of 27, of whom 5 were students in the Laura Memorial College, before its merger.

The State Association.—On May 10 the Ohio State Medical Association was incorporated at Columbus to federate the entire medical profession of the state by Charles S. Hamilton, Starling Loving, N. R. Coleman, D. N. Kinsman, T. W. Rankin, E. J. Wilson, W. D. Hamilton, and Frank Winders. The fiftieth annual meeting of the association was held in Cleveland, May 18, 19 and 20. The following officers were elected: President, Dr. Stephen S. Halderman, Portsmouth; vice-presidents, Drs. John S. Deemy, Bellefontaine, William E. Morris, Lisbon, and Adam H. McCollough, Mansfield; secretary, Dr. Frank Winders, Columbus; councilor, First District, Dr. Brooks F. Beebe, Cincinnati; councilor, Fifth District, Dr. T. Clarke Miller, Massillon, and delegates to the American Medical Association, Drs. John P. Sawyer, Cleveland, Jacob F. Marchand, Canton, and Thomas Hubbard, Toledo. Columbus was selected as the meeting-place for 1905.

PENNSYLVANIA.

Philadelphia.

Faure Holds Clinic.—Dr. J. L. Faure, the eminent French surgeon, conducted a clinic in the Jefferson Hospital on May 24, by request of Dr. W. W. Keen. He operated on a case of fecal fistula following appendicitis.

Hospital Appointments.—The following have been appointed to the resident staff of the Jefferson Medical College Hospital: Drs. J. H. Anderson, Louis Chodoff, E. W. Stevenson, Earle McLean, O. L. Wingate, F. C. Leytze, Atlee D. Mitchell and E. J. Porteus.

Sailed for Europe.—Dr. Charles F. Nassau sailed May 28. He will be absent about six weeks.——Dr. Gwilym M. Davis sailed May 28. He intends to study with Professor Bassini in Italy. ——Dr. E. Carlton Palmer sailed June 4. He will spend several months traveling on the Continent.

Class Reunion.—The class of 1894, Jefferson Medical College, held its first reunion in this city May 28. A permanent organization was effected, and the following officers were elected: President, Dr. William H. King; vice-president, Dr. Randall C. Rosenberger, and secretary and treasurer, Dr. Ward A. Brinton. It was decided to hold a reunion every five years.

Health Report.—Typhoid continues to decrease. There were only 120 cases reported for the week ended May 28, or 62 less than for the preceding week. There was a reduction of 23 cases of infectious disease and of 8 deaths, as compared with the previous week. Deaths from all causes numbered 494. This is an increase of 17 over the previous week.

Chemical Treatment of Water Unreliable.—Dr. Edward Martin, director of the department of health, has received from Dr. A. C. Abbott, chief of the health bureau, a review of the work done with chemicals in rendering water bacteria-free. He concludes that thus far this method can not be relied on. Chemical disinfection may, however, be resorted to until the city filter beds are completed.

Commencements.—At the seventy-ninth annual commencement of Jefferson Medical College, May 27, 165 young men were graduated. This brings the total number of graduates to 11,640; 26 different states were represented. The graduating class was addressed by George F. Baer, president of the board of trustees' of Franklin and Marshall College. Ninety-three members of the graduating class secured hospital appointments in competitive examination. The annual commencement of the medico-chirurgical College was held May 29, when 70 medical degrees were conferred. The doctorate oration was delivered by President Swain of Swarthmore College. In the medical graduates ten states were represented.

Hoffa in Philadelphia.—Dr. Albert Hoffa of the University of Berlin conducted a clinic in conjunction with Prof. H. Augustus Wilson, in Jefferson Medical College Hospital, May 25. Dr. Hoffa and his assistant, Dr. Hans Spitzy, were the guests of honor at the annual reception of the Jefferson Alumni Association in the evening. On May 26 Dr. Hoffa, by special request, conducted another clinic in the Jefferson Hospital. He performed two operations, one for paralysis of the arm, in a girl of 18, and another for coxalgia in a boy of 14. At the commencement of the Jefferson Medical College the honorary degree of LL.D. was conferred on Professor Hoffa. On June 6 he will hold a clinic on congenital dislocation of the hip in the Jefferson Hospital for the benefit of visiting members of the American Medical Association.

SOUTH CAROLINA.

County Election.—At the annual meeting of the Sumter County Medical Association, May 26, the following officers were elected: President, Dr. Julius A. Mood, Sumter; vice-presidents, Drs. William R. Mood, Summerton, and Charles P. Osteen, Sumter, and secretary and treasurer, Dr. Van Telburg Hofman, Sumter.

Colored Physicians Meet.—The Palmetto Medical Association held its eighth annual meeting at Florence, April 28. The following officers were elected: Dr. John M. Thompson, Charleston, president; Drs. I. A. Macon, Rock Hill, and J. Henry Alston, Summerville, vice-presidents; Dr. C. W. Birnie, Sumter, secretary, and Dr. William D. Crum, Charleston, treasurer.

Faculty Changes.—At the meeting of the trustees of the medical college of the State of South Carolina, Charleston, May 14, the following changes were made: The chair of clinical surgery and surgical pathology was abolished, and the chair of gynecology and abdominal surgery created, Dr. Manning Simons being elected to fill it; the chair of the practice of medicine and nervous diseases was established, Dr. Robert Wilson being assigned to it; the chair of obstetrics and diseases of children was created with Dr. Lane Mullally in charge; the chair of clinical and minor surgery was established, and Dr. A. Johnston Buist elected to fill it; the chair of physiology and clinical diseases of the eye, ear, nose and throat was established, to be filled by Dr. Edward F. Parker.

TENNESSEE.

Personal.—Dr. Hugh W. Tate, Bolivar, fell off a train recently and fractured a rib.——Dr. James J. Neely, Bolivar, has been promoted to the position of superintendent of the Western State Hospital for the Insane, Bolivar, and Dr. W. S. Cook, Whiteville, assistant superintendent.

Smallpox.—A deputy sheriff and his posse arrested 40 persons at a railroad camp near Clarksville, for violation of the quarantine law, by utter disregard of the orders of a physician who was attending a smallpox patient. Nine who had been exposed were vaccinated and the others were released.——Knox County now has more than thirty cases of the disease.

Many Receive Diplomas.—The fifteenth annual commencement of Tennessee Medical College, Knoxville, was held May 23, a class of eleven receiving diplomas from the dean, Dr. Charles McNabb. The doctorate address was delivered by Charles H. Brown, LL.D.——Knoxville Medical College graduated a class of six May 23. Rev. W. H. Franklin delivered the address of the evening and Dr. William H. Moore, dean of the faculty, presented the diplomas.

VIRGINIA.

Fined for Practicing Without License.—J. Wesley Colles, prosecuted at the instance of the Norfolk Medical Society, was fined $50 for practicing without a certificate from the state board.——Dr. J. T. Green, Bristol, was fined $50 for practicing medicine without a license.

More New Physicians.—University College of Medicine, Richmond, held its annual commencement, May 12. President Henry Louis Smith of Davidson College, N. C., delivered the doctorate address, and diplomas were awarded to a class of 25. ——The Medical College of Virginia, Richmond, held its sixty-sixth commencement exercises, May 10. Allen Caperton Braxtion of Staunton delivered the address of the evening.

Personal.—Dr. Benjamin L. Dillard, Alberene, was thrown from his buggy in a runaway accident and broke his leg below the knee.——The office of Dr. John F. May, Waverly, was among the buildings destroyed in the fire, May 17, which caused a loss of $60,000.——Dr. John H. Claiborne, Petersburg, has been appointed surgeon general of the Grand Camp of Confederate Veterans of Virginia, vice Dr. John S. Powell, Occoquan, deceased.

WISCONSIN.

Scarlet Fever in Wauwatosa.—The prevalence of scarlet fever in Wauwatosa has caused the closure of the first district school and the quarantining of the infected portion of the town. The health officers claim that the law has been flagrantly violated.

Personal—Dr Joshua C. Noyes, Oshkosh, fell in his house, May 20, and fractured his right femur ——Dr. William A Prouty has been elected city physician of Burlington

Caught in the Act.—"Dr" William E Aubin, Racine, was arrested, May 23, while in the act of making counterfeit coins at his house He said he was experimenting, but was held to await the action of the grand jury, under bond of $2,500 "Dr" Aubin pleaded guilty and was sentenced on May 31 to eighteen months' imprisonment in the Milwaukee House of Correction

New Doctors in Wisconsin—Wisconsin College of Physicians and Surgeons, Milwaukee, graduated a class of 29, May 26 Dr. Arthur J Burgess delivered the doctorate address, and Dr A. Hamilton Levings, the president, conferred the degrees ——A class of 23 was graduated from Milwaukee Medical College, April 30 Dr William H Earles, the president, conferred the degrees.

GENERAL

Yellow Fever at High Elevations—Dr L P Howard, entomologist of the Department of Agriculture, who has been investigating the subject in Mexico, believes it possible for yellow fever to occur on the higher levels which have been considered not liable to the disease

No Appeal from Naval Medical Board—Hereafter neither the President nor the Navy Department will entertain appeals from applicants for admission to the Naval Academy who have been rejected by the medical examining board for physical disabilities In the past considerable confusion has arisen from such protests

New York and Pennsylvania Transfers—Dr Henry Beates, president of the State Medical Examining Board, has announced that the board will give full credit in the Pennsylvania examinations for preliminary examinations taken in New York State This act had been withdrawn, but now transfers will once more be recognized

Insane Hospital Interne Wanted—The United States Civil Service Commission announces an examination, June 29 30, 1904, in various cities, for two medical internes in the Government Hospital for the Insane, Washington, D C, at $600 per annum each, and for other similar vacancies as they may occur in that hospital Further particulars may be had from the United States Civil Service Commission, Washington, D C, or from the secretary of a local board of examiners

Objectionable Medical Advertisements to be Excluded from Mails—The Post Office Department has determined to rid the mails of objectionable and offensive advertisements Those advertisements which are of an offensive nature will be excluded for violation of law as violating decency, and those which advertise fake preparations will be excluded on the ground of fraud on the public All drugs and nostrums will be referred to the Department of Agriculture for analysis to determine the sincerity of their medical claims, and the data in all cases will be finally referred to the Law Department for final action The action in this particular has received the approval and has the co operation of the American Newspaper Publishers' Association and a large number of medical men and scientists The attorney for the Post Office Department has held that any contract for advertisements of such objectionable matters is void when the Post Office Department has passed adversely on the character of the advertisement This decision will materially assist newspapers and publishing houses against suits for failure of contract to publish such advertisements when the Post Office Department declares the matter objectionable and excludes it from the mail The law in the matter is very broad, and is herewith appended

UNMAILABLE MATTER

Every obscene lewd or lascivious book pamphlet picture paper letter writing print or other publication of an indecent character and every article or thing designed or intended for the prevention of conception or procuring of abortion and every article or thing intended or adapted for any indecent or immoral use and every written or printed card letter circular book pamphlet advertisement or notice of any kind giving information, directly or indirectly, where or how or of whom or by what means any of the hereinbefore mentioned matters articles or things may be obtained or made whether sealed as first class matter or not are hereby declared to be non mailable matter and shall not be conveyed in the mails nor delivered from any post office nor by any letter carrier and any person who shall knowingly deposit or cause to be deposited for mailing or delivery anything declared by this section to be non mailable matter and any person who shall knowingly take the same or cause the same to be taken from the mails for the purpose of circulating or disposing of or of aiding in the circulation or disposition of the same shall, for each and every offense be fined on conviction thereof not more than five thousand dollars or imprisoned at hard labor not more than five years or both at the discretion of the court And all offences committed under the section of which this is amendatory, prior to the approval of this act may be prosecuted and punished under the same in the same manner and with the same effect as if this act had not been passed. Provided, That nothing in this act shall authorize any person to open any letter or sealed matter of the first class not addressed to himself

In a letter to our correspondent the first assistant postmaster general says that "the question of admission to the mails of newspapers containing medical advertisements treating of private and disgusting diseases, and offering for sale medicines designed for unlawful purposes, has already been considered by the department, and it has been decided that such advertisements are forbidden circulation in the mails by the act of Congress which declares to be unmailable 'any print or other publication of an indecent character, and every article or thing designed or intended for the prevention of conception' On presentation to the department of any advertisement such as above described, the same will be duly considered and appropriate action taken"

CANADA

Cambridge Recognition—Cambridge University has granted recognition to the medical course of Queen's University, Kingston, Ont Medical students at the latter institution, after spending one, two or three sessions there, may complete their course at Cambridge, full allowance being made for the full time they have put in at Queen's

Appointments at McGill.—The following appointments have been recently made in the medical faculty of McGill University Dr R Tait Mackenzie, lecturer in anatomy, Dr A A Robertson, lecturer in physiology, Dr W G M Rogers, lecturer in ophthalmology; Dr J W Scane, lecturer in pharmacology and therapeutics, Dr. W S Morrow, associate professor of physiology, Dr A G Nichols, associate professor of pathology and bacteriology

Personal—Dr and Mrs William Osler and family, Baltimore, will spend the summer at Murray Bay, Quebec Others who will be at Murray Bay this season are Drs Beech Jones, New York City, Hunter Robb, Cleveland, Ohio, and Johnson, Montreal ——Dr Harry J Watson, formerly of Toronto and Ottumwa, Iowa, later of the United States Army, at Manila, has commenced practice in Winnipeg, Man ——Dr J W Harris, of Toronto General Hospital, has been appointed relieving physician to the provincial insane asylums ——Dr Charles E Dogherty, assistant medical superintendent for the hospital for insane at New Westminster, B C, has resigned, to become superintendent of the hospital at the mining camp at Ymir —— Drs A B MacCallum and Wesley Mills, respectively professors of physiology at Toronto and McGill universities, have gone to Europe for the summer

FOREIGN

Nicaragua Quarantines Peru—The Pacific ports of Nicaragua have been closed against ships from Callao, at which point bubonic plague exists.

Isolation of Consumptives—The authorities at Breslau in charge of public hospitals have decided to rent a separate room for a consumptive in case it is deemed best to remove him from the family environment

Public Hospital for Venereal Diseases—Berlin has set apart a building with arrangements for 120 beds, to serve as a hospital for men and women (not prostitutes), who have to be treated for venereal diseases This is the second special station for these affections

Professors of Radiology—Vienna has taken the lead in inaugurating a chair of radiology in the medical faculty Dr Leopold Freund, Dr Robert Kienbock and Dr Guido Holzknecht have been appointed privat docents in the new branch The two latter have long been official *x* ray medicolegal experts for Austria

Renovation of the Berlin Charite—May 15 the new surgical ward in charge of Franz Konig was formally inaugurated with due ceremony The authorities have spared no pains to make this a model clinic in every respect, and to testify their appreciation of Konig's skill and record, a portrait bust is to be placed at the entrance

New Physiologic Institute at Vienna—Our Vienna exchanges comment with delight on the opening of the new building on the site of the old institute, the scene of Brucke's labors The new institute is proving a model one, admirably adapted for its purpose, and was erected without unnecessary delay and at a minimum of expense The entire cost of the building and equipment was only about $125 000 The air entering the amphitheater is forced through filters and artificially supplied with moisture

Street Named After Liebeault.—The street at Nancy where Liébeault lived until his death last February, has been named after him, and will be known henceforth as Rue du Docteur Liébeault. He was the founder of the Nancy school of hypnology, and was in his eighty-second year at the time of his death.

Tribute to Ehrlich.—On his return from America recently, Ehrlich was presented with a portrait medallion, the work of a well-known sculptor. The subscriptions had been collected by a group of sixty-five pupils and co-workers. He has been honored with the title of privy councilor, and is entitled to write "von" before his name. The occasion of the presentation was his fiftieth birthday, which occurred May 15.

Semicentennial of French Society of Medical Hydrology.—After a formal session the members of the society and its guests adjourned to a banquet to duly celebrate its semicentennial. Only one of the original founders of the society still survives, and he occupied the presidential chair. Most of the physicians of the watering-places throughout France belong to the society, which also includes a large number of general practitioners elsewhere, who wish to keep posted in regard to health resorts. Italy has also a similar society, modeled on the French one. The sixth annual study trip to the watering-places of France will start this year September 3 and disband September 15. It is in charge of Dr. Carron de la Carrière, 2 rue Lincoln, Paris. The watering-places of Vichy, Pougues and Lioran are on the list of places to be visited.

Return of Rieder from Turkey.—Six years ago Professor Rieder was invited to go to Turkey and organize a system of medical instruction there on a scientific basis. He was made chief medical inspector for the entire country, and inaugurated a number of important reforms. Four years ago he met with an accident affecting the spine, and is still suffering from its effects. He has resigned his position, and returns to Germany at the end of the school year, leaving the model Gülhane hospital in charge of his assistant, Professor Deycke. No one has been found to fill his place as president of the medical college. The Journal has occasionally reviewed the results of Rieder's work in Turkey as he has published them, and von Düring's communications on the subject of the amazing amount of syphilis in Asia Minor. Rieder's data and experiences have been collected in a large book just published entitled "Für die Turkei. Selbstgelebtes und Gewolltes."

Endemic Diseases in Japan.—Leprosy, smallpox, syphilis and ulcers, known as "ka-sa" in Japanese, are the four endemic contagious diseases of Japan. There are about 3,500 lepers in the total population of 35,000,000, and no attempt is made to isolate them. Smallpox is placarded by the family with a special sign, although there is no ordinance to compel it. Syphilis is about as common as in Europe, but severe tertiary accidents are rarely seen. Meyners d'Estrey, in an article in the *Revue Médicale du Canada* of May 4 attributes this benignity of the disease to the salubrious climate. He has observed that tertiary lesions are much more common and serious in Java where the climate is much hotter and more humid. This difference can not be ascribed to more intelligent medical care as until comparatively recently the physicians of Japan had not acquired a scientific knowledge of medicine. The practical study of anatomy has also been rendered very difficult by the laws and religious prejudices. Every two or three years the mikado would allow the autopsy of a criminal. On one of these occasions sixty-five physicians assembled from all parts of the empire. The operative skill of Japanese surgeons, with their hitherto meager anatomic knowledge is wonderful, and promises great surgical dexterity for the Japanese in time. An article on Japan's medical work in Formosa, written by a Japanese physician, was reviewed recently in these columns, page 931.

Correspondence.

Instruction in Psychiatry.

Philadelphia, May 28, 1904.

To the Editor;—In your editorial of to-day's issue of The Journal on "Instruction in Psychiatry," you failed to make any mention of the instruction which has been given for a number of years past in the Jefferson Medical College of Philadelphia. In the session of 1897-98 a systematic course, clinical and didactic, was given by myself, extending over the college term, beginning in the fall and continuing until the close of the college session; this course was voluntary. In the following year, that is in the session of 1898-99, attendance on these lectures became obligatory. In 1900 neurology and psychiatry were elevated to the position of a major branch, and an examination was required at the end of the session. The instruction is both didactic and clinical, the large number of cases in the insane department of the Philadelphia Hospital yielding abundant material for the work.

The examinations in psychiatry have been conducted with the examinations in neurology; six-tenths of each examination being devoted to neurology and four-tenths to psychiatry. As examples of the kind of questions asked at these examinations, I cite the following:

Enumerate the forms of mental disease which occur as sequelæ of typhoid fever.

What is dementia præcox? Into what forms is it divided? In what respects do the various forms differ from each other?

Enumerate the forms of nervous and mental disease produced by alcohol.

Describe the symptoms of melancholia. Give the differential diagnosis between melancholia and the depressive form of paresis.

Give the symptoms of delirium. Give the symptoms of mania.

What are the principal forms of paresis? Enumerate the more common physical signs of paresis.

Give the differential diagnosis between melancholia and paranoia.

Describe the symptoms of mania. What is the differential diagnosis between hypo-mania and the expansive stage of paresis?

Describe hebephrenia.

Describe circular insanity.

Describe paranoia.

Describe confusional insanity.

I may be permitted to add that for a number of years no student has passed through Jefferson College without having seen numerous cases of every one of the more common forms of mental disease, as well as instances of many of the rarer affections. One hour weekly is devoted to didactic instruction and one hour to clinical demonstrations. In this teaching I have the able assistance of Dr. William Pickett. The instruction in psychiatry is, of course, entirely apart from the instruction in neurology.

F. X. Dercum, M.D.,
Professor of Neurology and Psychiatry in the
Jefferson Medical College.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

PATENT MEDICINE ADVERTISING IN MAGAZINES.

Dr. D. E. Hills, Detroit, has had correspondence with *Everybody's Magazine* on the subject mentioned in The Journal, May 21, page 1367. He received the circular letter referred to and replied thereto, calling attention to objectionable advertisements. The reply of the publishers was of a very different tone from that which Dr. Todd received. They said that they would look into the merits of the Morley ear drum more carefully and that if the claims for it could not be substantiated, the wording of the advertisement would have to be changed or it would not be published. Dr. Hills remarks that in the June number of this magazine the advertisements of Madame Hessler, the ocularscope and the cartilage company do not appear. He suggests that the proprietors appear to be sincere in their efforts to cleanse their advertising pages from objectionable matter.

Marriages.

Frank Pearce, M.D., to Miss Summers, both of Tennessee.

Ernest Van Cott, M.D., to Miss Clara Bailey, both of Salt Lake City.

Seth Delmer Dice, M.D., to Miss Mary Little, both of Xenia, Ohio, May 25.

Francis C. Pache, M.D., to Miss Atola Wagner, at Ogden, Utah, May 11.

Charles Leonard Parkhurst, M.D., to Miss Mary D. Bell, both of Houstonia, Mo.

John D. Wakefield, M.D., to Miss Mary Brock, both of Loveland, Ohio, May 19.

Michael T. Collins, M.D., to Miss Maude Bosserman, both of Sedalia, Mo., May 19.

Richard Henry Lee, M.D., to Miss Florence Leonard, both of Kansas City, Mo, May 11.

Gilman Wilbert Petit, M.D., to Miss Harriette Mae Glover, both of Chicago, May 24.

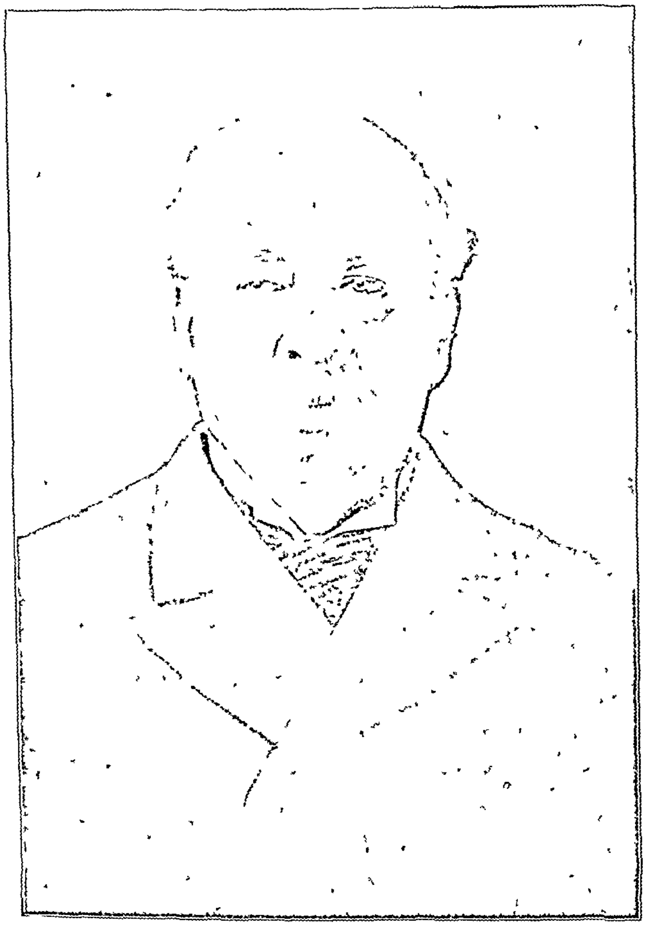
Samuel Watson Truitt, M.D., San Francisco, to Miss Edna Reinhardt of Missouri, at San Francisco, May 8.

Albertus Bentley Nichols, M.D., Wheeling, W. Va., to Miss Rose Clarissa Gallagher of Wilkesbarre, Pa., at Ellicott City, Md, April 9.

Deaths.

Ralph N. Isham, M.D.

Ralph Nelson Isham, M.D., one of the oldest and best-known surgeons in Chicago, died, May 28, at the home of his daughter in Lake Forest, from cancer of the stomach, aged 73 years. He was born in Manheim, N. Y., March 16, 1831, received his preliminary education at Herkimer Academy, Little Falls, N Y., and his medical degree from Bellevue Hospital Medical College, New York City, in 1854. He then served as house physician and surgeon in Bellevue Hospital, and after a trip abroad, settled in Chicago in November, 1855, and made it his permanent field of practice



Ralph Nelson Isham, M D

In 1859 he joined with Drs. N. S. Davis, John H. Hollister and the late Dr Edmund Andrews in the organization of the medical department of Lind University, which was later known as Chicago Medical College, now Northwestern University Medical School. In this institution he filled for many years the chair of surgical anatomy, operative surgery and surgery. During the Civil War he was one of the organizers and served as a member of the U S Sanitary Commission. He twice went South with supplies and physicians, and was in the field of the battle of Shiloh. *In 1862 he was appointed by President Lincoln* surgeon in charge of the Marine-Hospital, Chicago, which was then a military hospital, and continued in charge of this institution for several years after the war. He was surgeon of the Jewish Hospital, trustee of the North Star Dispensary, chief surgeon of the Chicago & Northwestern Railway Co., consulting surgeon to Cook County, Presbyterian and Passavant hospitals, a delegate to the International Medical Congress in London, in 1881, and major and surgeon of the First Infantry, Illinois *National Guard*, etc.

He was a member of the American Medical Association, a life member of the Chicago Medical Society, and an honorary member of the New York Medical Society. He also received honorary degrees from the University of the *City of New York* and the Northwestern University.

He was in active practice until about six years ago, when he retired, and since that time has spent much of his time in travel. Dr. Isham was noted for his erudition, both in and out of the medical profession, and possessed what is said to be one of the finest private libraries in Chicago.

F. Savary Pearce, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1891, one of the most prominent young neurologists of Philadelphia; a member of the American Medical Association from 1899 to 1903, inclusive, secretary, and at the time of his death, chairman of the Section on Nervous and Mental Diseases; a member of the Medical Society of the State of Pennsylvania, Philadelphia County Medical Society, Philadelphia Neurological Society, Philadelphia Pathological Society, and Eastern Ohio Medical Association; a fellow of the College of Physicians of Philadelphia, and treasurer of the Philadelphia Medical Club; professor of nervous and mental diseases in the Medico-Chirurgical College of Philadelphia; neurologist to the Philadelphia and Howard hospitals, died at the home of his parents in Steubenville, Ohio, May 27, from nervous collapse, due to persistent overwork, aged 36. His portrait appears in the supplement to this issue of The Journal among the section officers. His latest contribution to the literature was his "Practical Treatise on Nervous Diseases," which appeared in March of this year. In last week's issue of The Journal it was noted that Dr. Pearce had gone away for rest to his parents' home in Steubenville.

Thomas Murray Drysdale, M.D. Pennsylvania Medical College, Philadelphia, 1852, a member of the American Medical Association since 1873; one of the founders of the American Gynecological Society; member of the Philadelphia County Medical Society since 1853, vice-president in 1875, and president in 1876; member of the Medical Society of the State of Pennsylvania since 1864, and corresponding secretary in 1873-1874; vice-president of the American Academy of Medicine in 1882; member of the International Medical Congress in 1876; member of the Philadelphia Pathological Society; member, vice-president, and twice president of the Philadelphia Obstetrical Society; member of the Philadelphia College of Physicians and of the British Medical Association; surgeon of the First Pennsylvania Volunteer Infantry in the Civil War; consulting surgeon to Girard College; consulting gynecologist to the Medico-Chirurgical Hospital; died at his home in Philadelphia, May 26, from pneumonia, aged 72

Henry Downer Ingraham, M.D. University of Buffalo Medical Department, 1866, a member of the American Medical Association, Medical Society of the State of New York, American Association of Obstetricians and Gynecologists, and other societies; gynecologist to three hospitals in Buffalo; professor of practice of medicine in the University of Buffalo from 1898 to 1902, died at his home in Buffalo, May 23, after a protracted illness, aged 62.

University of Louisville, 1864, surgeon of the Fifty-fourth Kentucky Volunteer Infantry in the Civil War, president of the Louisville School Board in 1891, professor of theory and practice of medicine in the Kentucky School of Medicine, died at his home in Louisville, May 18, from Bright's disease, after an illness of three months, aged 70.

Edwin Galliard Mason, M.D. Bellevue Hospital Medical College, New York City, 1887, of New York City, assistant professor of nervous diseases of the New York Polyclinic; for eight years editor of *Galliard's Medical Journal;* since 1900 vice-president of the New York County Medical Society, died at his father's home in Hagerstown, M.D., May 24, aged 39.

Philander Daugherty, M.D. Rush Medical College, Chicago, 1886, a member of the American Medical Association; mayor *of Junction City, Kan.,* in 1897 and 1898; representative in the state legislature from Geary County in 1892; health officer of Junction City for several years, died at his home in that place, May 23, from apoplexy, aged 70.

Reginald Henwood, M.D. College of Physicians and Surgeons of Toronto, 1877, of Ontario, died, May 22, at his home in Brantford, aged 76. He secured his provincial license to practice in Ontario in 1846, and for more than fifty years practiced at Brantford, retiring in 1900. He was mayor of the city in 1882 and 1883.

Peter Evans Griffin, M.D. University of Pennsylvania, Philadelphia, 1855, surgeon of the Third Regiment South Carolina State Troops in the Civil War; for 13 years superintendent of the State Hospital for the Insane, died at his home in Columbia, S. C., May 18, from paralysis, aged 73.

Jared W. Daniels, M.D., Massachusetts, 1854, a pioneer of St. Peter, Minn., surgeon of the Sixth Minnesota Volunteer Infantry in the Civil War, who retired from practice in 1888, died at his home in Los Angeles, Cal., May 10, from pneumonia, after an illness of five days, aged 76.

Robert Johnston, M.D. Medical College of Ohio, Cincinnati, 1862, surgeon of the One Hundredth Ohio Volunteer Infantry in the Civil War, and for two months a prisoner in Libby Prison, died suddenly from apoplexy at his home in Milford, Mich., May 14, aged 65.

Robert Henry Stirling, M.D. University of Maryland, Baltimore, 1859, acting assistant surgeon, U. S. Army during the Civil War, died suddenly at his home in Baltimore, May 24, from heart disease, aged 67. He retired from practice in 1876.

Merritt Hard Cash Vail, M.D. New Jersey, 1853, surgeon of the First New Jersey Volunteer Infantry in the Civil War, of Long Beach, Cal., died suddenly from paralysis at the Deaconess Hospital, Los Angeles, May 19, aged 75.

David P. Jackson, M.D. College of Physicians and Surgeons, New York City, 1865, for several years coroner of Broome County, N. Y., and health officer of Binghamton, died at his home in that city, May 23, aged 63.

George W. Weems, M.D. University of Maryland School of Medicine, Baltimore, 1854, surgeon in the confederate service during the Civil War, and in the Crimean War, died at his home near Huntsville, Mo., May 13.

William W. Wickham, M.D. McGill University Medical Department, Montreal, 1895, of Tignish, P. E. I., died at Ste. Agathe, Quebec, where he had gone three months ago in search of health, on May 14, aged 36.

Charles Warren White, Jr., M.D. Bellevue Hospital Medical College, New York City, 1885, died at his home in Fairhaven, Mass., May 15, after an illness of one day, following an emergency operation, aged 44.

A. E. Williams, M.D. Medical College of the State of South Carolina, Charleston, 1854, a veteran of the Civil War, died at his home in Cottageville, S. C., May 18, after a long period of ill health, from paralysis.

Theodore C. West, M.D. College of Physicians and Surgeons of Chicago, 1900, of Troy, Idaho, died at Lidgerwood Sanitarium, Spokane, Wash., May 15, from typhoid fever, after an illness of three weeks.

W. O. Alexander, M.D. University of Georgetown (D. C.) Medical Department, died at his home in Washington, D. C., from organic heart disease, May 23, after an illness of several months, aged 57.

Frank P. Blair, M.D. Albany (N. Y.) Medical College, 1877, of Allegany, N. Y., died at the Olean General Hospital, May 21, two days after an operation for malignant disease of the bladder, aged 61.

Asa H. Tyler, M.D. assistant surgeon of the Sixty-eighth Ohio Volunteer Infantry in the Civil War, died at his home in Napoleon, Ohio, May 23, from Bright's disease, after a short illness, aged 85.

James M. McNutt, M.D. Washington University School of Medicine, Baltimore, 1869, an ex-Confederate soldier, died at his home in Eastville, Va., May 23, by poisoning from wood alcohol, aged 60.

William C. Burden, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1876, formerly president of the Rice County (Kan.) Medical Association, died recently at his home in Sterling, aged 52.

Bushnell A. Wright, M.D. Ohio, 1873, for nine years superintendent of the Toledo (Ohio) State Hospital, died suddenly at his home in Los Angeles, Cal., May 17, from cardiac neuralgia, aged 81.

Tyler W. Richmond, M.D. University of Michigan, Ann Arbor, 1874, postmaster of Bear Lake, Mich., for twelve years, died at his home in that place, and was buried May 15, aged 56.

Roberdeau Harmon, M.D. University of California Medical Department, San Francisco, 1879, died suddenly at his office in Oakland, Cal., May 19, from fatty degeneration of the heart.

Chauncey Howard Kinnaman, M.D. Jefferson Medical College, Philadelphia, 1886, died at his home in Cleveland, Ohio, May 22, from heart disease, after a long illness, aged 46.

Thomas J. Fitzmaurice, M.D. Bellevue Hospital Medical College, New York City, 1893, an alderman of Paterson, N. J., died at his home, May 20, from liver disease, aged 35.

Lewis B. Andrews, M.D. University of Buffalo Medical Department, 1885, died at his home in Rochester, N. Y., May 21, from pneumonia, after an illness of two weeks, aged 40.

Herbert C. Featherston, M.D. McGill University Medical Department, Montreal, died from pleuro-pneumonia, after a long illness, April 8, at his home in Toronto, aged 25.

Delavan E. Walker, M.D. University of Buffalo (N. Y.) Medical Department, 1882, died at his home in Ilion, N. Y., May 18, after an illness of several months, aged 49.

Rolland T. Dean, M.D. Medical College of Ohio, Cincinnati, 1872, died at his home in New Sharon, Iowa, May 22, from apoplexy, after an illness of ten days, aged 81.

Richard G. Lightle, M.D. Kentucky School of Medicine, Louisville, 1898, was burned to death in his barn, in Searcy, Ark., May 22, by the explosion of a lamp, aged 32.

Francis X. Patoel, M.D. Trinity Medical College, Toronto, 1872, died at his home in Willimansett, Mass., May 11, from bronchitis, after a short illness, aged 58.

James M. Waddell, M.D. Bellevue Hospital Medical College, New York City, 1864, died from Bright's disease at his home in Penn Yan, N. Y., May 15, aged 69.

Malcolm White, M.D. Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, 1901, died suddenly at a hotel in Ashburn, Mo., May 17.

Jonathan J. Wright, M.D. Cincinnati College of Medicine and Surgery, 1854, died at his home in Emporia, Kans., May 13, from heart disease, aged 74.

Henry N. Stanley, M.D. University of Louisville, 1881, died at his home in Atlanta from heart disease, after ten years of ill health, May 23, aged 44.

Charles Hugh Murray, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasgow, 1889, formerly of Port Rush, Ireland, died at Mentone, Cal., March 9, aged 40.

Herbert C. Williams, M.D. College of Physicians and Surgeons, Baltimore, 1882, died at his home in Sanford, N. C., May 16, after a long illness.

Margaret Preston Duckman, M.D. Woman's Medical College, Philadelphia, died at her home in Trenton, N. J., January 7, from scarlet fever.

John F. James, M.D. Western University Medical Department, London, Ont., 1895, died at his home in Ionia, Mich., May 15, aged 38.

Robert La Grange, M.D. Rush Medical College, Chicago, 1871, died at his home in Marion, Iowa, May 23, after an illness of about one year.

Michael Enright, M.D. Rush Medical College, Chicago, 1881, died suddenly from heart disease at his home in Akron, Colo., April 8.

Thomas Barnett, M.D. Rush Medical College, Chicago, died at his home in Fort Scott, Kan., May 19, from heart disease, aged 72.

John E. Maucher, M.D. University of Munich, Germany, 1851, died at his home in Carrolltown, Pa., May 21, from old age, aged 78.

Truman D. Nichols, M.D. New York, 1852, committed suicide by taking hydrate of chloral, May 14, at his home in Ripley, Okla.

Charles R. Jones, M.D. Ohio, 1876, died at his home in Jonesboro, Ind., May 19, from paralysis, after an illness of two years.

M. Taylor Powell M.D. College of Physicians and Surgeons, Baltimore, 1883, died at his home in Newburg, W. Va., May 15.

John B. Pettingill, M.D. University of Pennsylvania, Philadelphia, 1870, died at his home in Chicago, March 22, aged 59.

Charles Mudge, M.D. College of Physicians and Surgeons, New York City, 1888, died recently at his home in Phelps, N. Y.

Henry Huntington, M.D. Albany (N. Y.) Medical College, 1866, died at his home in National City, Cal., April 27, aged 85.

Alvin M. Woodward, M.D. New York, 1862, died at his home in New York City from intestinal disease, May 21, aged 68.

Frank G. Fuller, M.D., died at the home of his son in Mountville, S. C., May 22, after an illness of ten days, aged 82.

Fred Welch, M.D. Dartmouth Medical College, Hanover, N. H., 1893, died at his home in Olatha, Colo., Nov. 16, 1903.

John Ellwood Peters, M.D. Pennsylvania, 1875, died from apoplexy at his home in Jenkintown, Pa., May 16, aged 49.

Silas Griffith, M.D. Pennsylvania, 1866, of Philadelphia, died at Glen Moore, Pa., May 21, from apoplexy, aged 75.

J. P. Gilbreath, M.D., who had practiced for more than 50 years in Fallsburg, Ohio, died, May 16, aged 84.

Cornelius Van Evia, M.D., died suddenly at his home in Vineland, N. J., from apoplexy, aged 72.

Philo L. Hatch, M.D. Ohio, 1857, died at his home in Santa Barbara, Cal., May 21, aged 81.

Charles J. Cooper M.D. Ohio, 1902, died recently at his home in Penfield, Ill.

Association News.

THE ATLANTIC CITY SESSION.

The Deposit of Railroad Tickets—Instructions for Registration.

On arrival in Atlantic City or soon thereafter, members and any others who travel on the excursion tickets should leave their tickets with Mr. H. C. Blye, joint agent, at Morris Guards' Armory, 12 South New York Avenue, Atlantic City. On the day of departure, and not before, the ticket is to be claimed, and will then be signed by the joint agent. Tickets not thus deposited and signed will not be good for return passage.

On reaching Philadelphia, if stopover is desired, the ticket must be deposited in Philadelphia and taken up again on the day of departure. In any case, the holder must start on the homeward journey from Philadelphia June 13. There is a possibility that arrangements may be made for extension of time, but this is not probable enough to be depended on.

The latest information as to stopovers is that stopover will be allowed on the going trip as first announced.

Registration at Atlantic City—Some Suggestions.

The Registration Bureau will be open for the registration of members at 8 o'clock Monday morning, June 6, and will remain open until 5:30 p. m. These hours will prevail each day until Friday, June 10, when the hours will be from 9 to 11 a. m., the bureau closing at 11.

Members will do well to go to their hotels immediately on arriving, and, having located, to the bureau and register.

The method of registration is as follows: Members will find cards at the bureau, which they will fill out. These cards are double; the upper relates particularly to registration and the attached card is intended for two purposes—the first to indicate the section with which the member desires to affiliate himself, and the second will be the basis for the list that will be published in THE JOURNAL after the session. When these cards are filled out, the member will present them at the indicated window, and if he has paid his dues for 1904, he will show his "pocket card." If he has not paid his dues for 1904, he will present the registration cards at a cash window and there pay the amount due.

Members are urged to take with them their pocket cards. It will save them, as well as the clerks at the Registration Bureau, much annoying delay.

NEW MEMBERS.

Physicians who desire to join the Association at Atlantic City must bring with them a certificate showing they are members of their state association or of one of its component branches. This is important. The certificate should be signed by the president and secretary of the state association or by the president and secretary of a component society.

House of Delegates.

The House of Delegates will be called to order promptly at 10 a. m., Monday, June 6, at the High School Building. The Committee on Credentials and Registration will be at the High School Building at 9 a. m. for the registration of the members of the House of Delegates. Members are urged to be present at 9 o'clock, or as soon after as possible, so that the registration may be completed by the time the meeting is called to order.

Rush Monument Dedication.

The announcement last week that the dedication of the Rush monument would be at 4 p. m., Saturday, June 11, was an error. The hour fixed is 5 p. m.

SCIENTIFIC EXHIBIT.

Program of Demonstrations To Be Given at the Atlantic City Session.

Dr. Frank B. Wynn, Indianapolis, director, announces the following program of demonstrations to be given on Wednesday and Thursday afternoons on Young's Pier.

WEDNESDAY, JUNE 8—2 P. M.

1. Some Phases of Surgical Pathology. Charles H. Frazier, Philadelphia.
2. Arteriosclerosis and Consecutive Visceral Lesions. William H. Welch, Baltimore.
3. Series of Heart Lesions. J. E. Greiwe, Cincinnati.
4. Lesions of Tuberculosis, Human and Animal. W. M. Late [illegible] C. Y. White.

[illegible], Illustrating [illegible] and Means [illegible]

6. Series of Brain Lesions. D. J. McCarthy, Philadelphia.
7. Art Work in Pathologic Anatomy. I. W. Blackburn, Washington, D. C.
8. Miscellaneous Demonstrations.

THURSDAY, JUNE 9—2 P. M.

9. Hodgkin's Disease. Warfield T. Longcope, Philadelphia.
10. Lesions in Diseases of the Kidney. W. M. Late Coplin, Philadelphia.
11. [illegible] Aleppo Boil, Scarla[illegible] [illegible]oston.
12. [illegible] Pathologic Conditions (Typhoid, Ch[illegible], Diphtheria and Neuralgia). Henry A. Christian, Boston.
13. Demonstration of Some Lesions of Non-tuberculous Chronic Arthritis. Edward H. Nichols, Boston.

Demonstrations 11, 12 and 13 will be chiefly by means of lantern slides. At the close of the afternoon session the enlargements of photomicrographs from the Department of Pathology of the Harvard Medical School will be informally demonstrated by Drs. Councilman, Nichols and Christian.

14. Forms of Food Adulteration. Especially of Imported Food Products. H. W. Wiley, Washington.

PHYSIOLOGIC EXHIBITS.

15. (a) New [illegible] [illegible] S. Hall, Chicago.
16. (b) Harv[illegible] W. B. Cannon, Boston.
17. (c) Model [illegible] Central Nervous System. Gaylord P. Clark, Syracuse, N. Y.
18. (d) Specimens of Suprarenal Grafting. F. C. Busch, Buffalo.

Miscellaneous demonstrations.

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending May 28, 1904:

Henderson, Albert B., asst.-surgeon, ordered to report about June 15, 1904, to Colonel Wm. M. Wallace, Fifteenth Cavalry, president of the Army Retiring Board at the War Department in Washington, for examination by the board.

Davis, William R., Owen, Leartus J., Zinke, Stanley G., Culler, Robert M., Weed, Frank W., and Wickline, Wm. A., first lieutenants and asst.-surgeons, appointed to rank as such from May 19, 1904.

Williamson, L. P., asst. surgeon, in addition to present duties pertaining to the Louisiana Purchase Exposition, St. Louis, is announced as attending surgeon at the Northern Division Headquarters in that city.

Stiles, Henry R., asst.-surgeon, reported for treatment at U. S. Army General Hospital, Presidio of San Francisco.

Woodbury, Frank T., asst.-surgeon, granted twenty days' leave of absence.

Truby, W. F., asst.-surgeon, granted thirty days' leave of absence.

Edie, Guy L., surgeon, reported for and assigned to duty in S. G. O. in charge of the sanitary and disbursing division and as disbursing officer, medical department, assignment to the Philippine Islands being revoked.

Steer, Sam'l L., asst.-surgeon, granted eighteen days' leave of absence about June 1, 1904.

Board convened at Norfolk, Va., May 31, 1904, for the examination of Pharmacist L. P. Hall to determine his fitness for promotion to the grade of pharmacist of the second class. Detail for the board: Surgeon J. B. Stoner, chairman; Asst.-Surgeon J. S. Boggess, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from May 21 to May 27, 1904:

SMALLPOX—UNITED STATES.

California: San Francisco, May 8-15, 1 case.
District of Columbia: Washington, May 15-21, 6 cases.
Florida: Jacksonville, May 15-21, 1 case.
Georgia: Macon, May 15-21, 4 cases.
Illinois: Danville, May 15-21, 2 cases.
Kentucky: Covington, May 15-21, 1 case.
Louisiana: New Orleans, May 15-21, 12 cases, 1 imported.
Michigan: Detroit, May 15-21, 1 case.
Missouri: St. Louis, May 15-21, 11 cases.
Nebraska: Omaha, May 15-21, 3 cases, 1 death.
New Hampshire: Manchester, May 15-21, 4 cases.
Ohio: Toledo, May 15-21, 1 case.
Pennsylvania: Pittsburg, May 18-24, 3 cases.
South Carolina: Charleston, May 16-21, 3 cases.
Wisconsin: Milwaukee, May 15-21, 8 cases.

SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, April 11-24, 133 cases, 63 deaths.

Canada: Sydney, May 15-21, 1 case.

China: Hongkong, March 26-April 2, 6 cases, 5 deaths, Shanghai, March 25-April 2, 8 deaths.

France: Marseilles, April 1-30, 5 deaths.

Great Britain: May 8-14, Birmingham, 1 case; Bristol, 1 case; Leeds, 3 cases; Liverpool, 1 case; May 1-7, Edinburgh, 5 cases; Hull, 1 case; Glasgow, May 7-13, 25 cases, 1 death; London, May 1-14, 40 cases, 1 death; New Castle-on-Tyne, May 1-17, 3 cases, 1 death; Nottingham, April 24-May 7, 8 cases..

India: Bombay, April 20-26, 23 deaths; Karachi, April 18-24, 9 cases, 1 death.

Italy: Catania, May 6-12, 1 death; Palermo, May 1-7, 2 cases.

Japan: April 1-9, Moji, present; Nagasaki, epidemic; Sasebo, present.

Java: Batavia, April 10-16, 11 cases, 1 death.

Mexico: May 8-14, Tampico, 1 death: Torreon, 5 cases, 5 deaths.

Netherlands: Rotterdam, May 8-14, 1 death.

Russia: Moscow, April 24-30, 7 cases, 4 deaths; Odessa, April 11-24, 5 cases, 1 death; St. Petersburg, April 24-May 7, 32 cases, 8 deaths; Warsaw April 10-23, 53 deaths.

Straits Settlements: Singapore, March 26-April 2, 1 death.

Turkey: Alexandretta, May 1-7, epidemic; Beirut, April 24-30, present; Constantinople, May 2-8, 6 deaths.

SMALLPOX—INSULAR.

Philippine Islands: Cebu, March 1-31, 1 case, 1 death; Manila, March 27-April 2, 1 case.

YELLOW FEVER.

Brazil: Rio de Janeiro, April 11-24, 7 deaths.

Ecuador: Guayaquil, April 24-May 4, 5 deaths.

Mexico: Coatzacoalcos, May 11-17, 3 cases, 1 death; Merida, April 24-30, present; Vera Cruz, May 8-21, 3 cases.

CHOLERA.

India: Bombay, April 20-26, 1 death; Madras, April 16-22, 1 death.

Persia: Kermanschah, to April 11, 20 deaths.

PLAGUE—FOREIGN.

Africa: Johannesburg, May 5, 2 cases; Port Elizabeth, April 17-23, 2 cases, 1 death.

Australia: Brisbane, April 8-16, 2 cases.

Brazil: Nichtheroy, April 15, 1 case, 1 death; Para, April 24, still present; Rio de Janeiro, April 11-24, 5 deaths.

Chile: Antofogasta, April 19, 9 cases.

China: Hongkong, March 26-April 2, 3 deaths.

Formosa: March 31-April 9, 229 cases, 167 deaths.

India: Bombay, April 20-26, 532 deaths; Madras, April 16-22, 1 death.

Peru: Lima, April 10-11, 20 cases.

Straits Settlements: Singapore, March 27-April 2, 1 death.

PLAGUE—INSULAR.

Philippine Islands: Cebu, March 1-31, 3 cases, 3 deaths; Manila, March 25-April 2, 1 case.

Wisconsin State Medical Society, Milwaukee, June 22.

AMERICAN CONFEDERATION OF RECIPROCATING EXAMINING AND LICENSING MEDICAL BOARDS.

Third Annual Meeting, held in Chicago, May 24, 1904.

The President, Dr. W. A. Spurgeon, Muncie, Ind., in the Chair.

Dr. George H. Simmons, Chicago, delivered the address of welcome on behalf of the local profession. The response was delivered by Dr. Chester Mayer, member of the Kentucky State Board of Health.

The following states are members of this confederation: Wisconsin, Indiana, Michigan, Ohio, Iowa, Georgia, Kansas, Illinois, Nebraska, Kentucky, Maryland, New Jersey and Pennsylvania (Eclectic).

There were present at the meeting:

Michigan: J. H. Cowell, Saginaw, president; B. D. Harison, Sault Ste. Marie, secretary; Wm. Bell, Belding; H. B. Landon, Bay City; Geo. Ranney, Lansing.

Indiana: W. A. Spurgeon, Muncie, vice-president; W. J. Gott, Crawfordsville, secretary; L. C. Webster.

Wisconsin: J. R. Currans, Two Rivers, president.

Iowa: J. A. McKlveen, Chariton, president.

Kentucky: Chester Mayer, Louisville.

Maryland: J. McP. Scott, Hagerstown.

Illinois: Geo. W. Webster, Chicago, president

Nebraska: Benj. F. Bailey, Lincoln, president.

President's Address.

Dr. Spurgeon recommended that every state medical practice act should empower the state board to enter into reciprocal relations with other states. He said that to get reciprocity, no state should stand aloof on account of inability to participate fully in all the advantages to be obtained from reciprocity; a state should reciprocate in such cases as are eligible. To adjust differences, there should be appointed a board of arbitration, whose duty it would be to hear and decide disputed questions. To the end that reciprocity may become more general, a committee should be appointed to determine the best course for securing reciprocity clauses in the laws of such states as have no such provisions. He suggested further, that the confederation give full consideration to and reach some conclusion in the matter of the plan adopted by some medical colleges and universities of granting a combined baccalaureate and medical degree in six years. All the literary colleges in the country may consistently demand the same privilege, which would result in the establishment of many new medical colleges all over the states.

The discussion on the recommendations contained in the address was very full, and, in the main, hinged on the necessity of bringing about conditions that would permit of full reciprocity between the various states in the matter of medical registration and licensing. To this end it was considered necessary that there should be uniform entrance requirements in all the medical colleges, uniform standard curricula, uniformity in the nature and conduction of state board examinations for licensure, with such additions as each board may see fit to make.

The basis for reciprocal registration under which the confederation is now working is the following:

(A) As a prerequisite to reciprocal registration, the applicant shall file in the office of the board of the state of which he is a licenciate such evidence as will enable the said board to certify that he is of good moral and professional character. Such certificate shall be filed with his application for reciprocal registration in another state.

(B) (Qualification 1). A certificate of registration showing that an examination has been made by the proper board of any state, on which an average grade of not less than 75 per cent. was awarded, the holder thereof having been at the time of said examination the legal possessor of a diploma from a medical college in good standing in the state where reciprocal registration is sought, may be accepted in lieu of examination, as evidence of qualification. Provided that in case the scope of the said examination was less than that prescribed by the state in which registration is sought, the applicant may be required to submit to a supplemental examination by the board thereof in such subjects as have not been covered.

(C) (Qualification 2). A certificate of registration or license issued by the proper board of any state may be accepted as evidence of qualification for reciprocal registration in any other state. Provided that the holder of such certificate had been engaged in the reputable practice of medicine in such state at least one year; and also provided that the holder thereof was, at the time of such registration, the legal possessor of a diploma issued by a medical college in good standing in the state in which reciprocal registration is sought, and that the date of such diploma was prior to the legal requirement of the examination test in such state.

The following committees were appointed to report at the next meeting:

Committee on uniformity as to the scope and character of examinations to be held by state boards of health and examining boards: Chester Mayer, Kentucky; L. C. Webster, Indiana, and Geo. W. Webster, Illinois.

Committee on uniform requirements, both entrance and graduation, to be demanded of medical colleges: B. F. Bailey, Nebraska; B. D. Harison, Michigan, and J. McP. Scott, Maryland.

Committee on advanced standing: J. F. McKlveen, Iowa; J. R. Currans, Wisconsin, and H. B. Landon, Michigan.

Committee on uniformity of application blanks and forms: The secretaries of examining boards and the secretary of this confederation.

Conference committee to meet with similar committees from the American Medical Association, Association of American Medical Colleges, Southern Medical College Association, National Confederation of State Licensing and Examining Boards, American Institute of Homeopathy, National Eclectic Medical Association and National Physio-Medical Association of Physicians and Surgeons.—Geo. W. Webster, Illinois.

The next meeting of the confederation is to be held in St. Louis, Mo., Oct. 25, 1904. The present officers are to hold over until then.

ASSOCIATION OF AMERICAN PHYSICIANS.

Nineteenth Annual Meeting, held at Washington, D. C., May 10-11, 1904.

(Concluded from page 1443.)

The Relation of Cells with Eosinophile Granulations to Bacterial Infection.

Dr. E. L. Opie, Baltimore, read this paper. In the course of the bacterial infections the easinophile cells are predominant in the local reaction, but disappear from the peripheral circulation. In the non-bacterial infections, such as smallpox and scarlet fever, on the other hand, the eosinophile cells are increased. The experiments through which these conclusions were reached were performed on guinea-pigs, using the *Bacillus pyocyaneus* and the *Bacillus mucosus capsulatus*, among others. In the acute infections the eosinophile cells disappear from the peripheral circulation rapidly, within twenty-four hours in the case of infection with *Bacillus pyocyaneus*. These cells gradually returned to the circulation, and, on the fifth or sixth day after the infection, reached their maximum number; by the eighth day they had fallen to their normal percentage. This process suggests a destruction of the eosinophiles, followed by their regeneration. After the eosinophile cells have passed from the blood vessels into the surrounding tissues they were found to undergo a nuclear degeneration and then to become ingested by the large mononuclear leucocytes, the macrophages of Metchnikoff. Eosinophilous myelocytes were found in the venous sinuses of the spleen after infection with the microorganisms referred to. Later they became less numerous, and within twenty-four hours had entirely disappeared. This fact was interpreted to mean that these cells originate in the bone marrow, and are temporarily held in the spleen. The opinion is advanced that the bacteria employed in this study are positively chemotactic for the eosinophile cells, attracting them from the bone marrow to the site of the inoculation. The eosinophile cells accumulate near the bacteria, and play some part in the series of changes following the invasion.

DISCUSSION.

Dr. S. J. Meltzer, New York City, said that there is a distinct contrast between the action of animal parasites and that of bacteria on these cells. He believes that the toxins of both classes of parasites are chemotactic for both kinds of leucocytes, but that in the case of the animal parasites the eosinophile cells predominate, while in the case of the bacteria the neutrophile cells predominate. This may be a way to determine which diseases are due to animal parasites and which are due to bacteria.

A New Case of Chloroma with Leukemia, with a Study of the Cases Reported since 1893.

Drs. George Dock and Alfred S. Warthin, Ann Arbor, Mich., read this paper. Clinically, chloroma is characterized by the development of an anemia without apparent cause, emaciation, loss of strength, exophthalmos, strabismus, hemorrhages and the occurrence of tumors. The case reported occurred in a man, aged 45 years, who began to get weak and to have a rapid pulse. He was thought to have pernicious anemia; there was neither lymphatic nor splenic enlargement. There was a leucocytosis of 35,000; the blood had the appearance of lymphatic leukemia; and greenish tumors developed in various parts of the body. A differential count of the leucocytes showed the presence of 6 per cent. lymphocytes, 3 to 4 per cent. large lymphocytes, 1 per cent. eosinophiles, 0.1 to 0.2 per cent. mononuclear eosinophiles, 0.1 to 1.9 myelocytes, 0.4 per cent. basophiles, and 80 per cent. of cells different from those seen in normal blood, but like the normal bone marrow cells. Normoblasts and megaloblasts were found. The original diagnosis made was acute lymphatic leukemia of gastrointestinal origin, but later this was revised to chloroma. The disease appears to be more common in men than in women; the average age of the patients is 18.8 years; the average duration six months. In 13 cases the blood presented the appearance of that of acute lymphatic leukemia, except in one case in which the leucocytes numbered only 8,000. The relation of chloroma to leukemia is decided, but the complete resemblance is not always found. The cause of the color of the tumors is not known. In one of the reported cases the sediment of leucocytes was green in color, and the clots found in the heart after death were green in color. The growths have the structure of leukemic growths in general, and they sometimes contain large numbers of eosinophilic cells. The tumors arise primarily from the bone marrow, the neoplastic hyperplasia having its starting point in the parent cells of the large lymphocytes. These cells being undifferentiated, easily break down and explain some of the histologic blood findings. It is suggested that the condition is a malignant form of leukemia, due to deficient blood formation and not to excessive hemolysis.

DISCUSSION.

Dr. William Osler, Baltimore, said that the clinical picture of chloroma is so different from that of acute leukemia that a sharper differentiation should be made between the two diseases.

Dr. S. J. Meltzer, New York City, asked if albumose had been found in the urine in the case reported. He also asked whether the tumors were always found in connection with the bones of the axial skeleton.

Dr. George Dock said that albumose was not looked for in the urine of his patient: it has sometimes not been found in those cases in which it has been looked for. In cases examined thoroughly some of the bones of the appendicular skeleton have been the seat of tumor formation. The distribution is irregular, however. The term myeloma is unsatisfactory.

(To be continued.)

AMERICAN GYNECOLOGICAL SOCIETY.

Twenty-ninth Annual Meeting, held in Boston, May 24-26, 1904.

The society met in the Boston Medical Library under the presidency of Dr. Edward Reynolds, Boston.

An address of welcome was delivered by Dr. Charles M. Green, Boston, which was responded to by Dr. Henry T. Byford, Chicago.

Officers Elected.

The following officers were elected: President, Dr. E. C. Dudley, Chicago; vice-presidents, Drs. Henry D. Fry, Washington, D. C., and Henry C. Coe, New York City; secretary, Dr. J. Riddle Goffe, New York City; treasurer, Dr. J. M. Baldy, Philadelphia.

Niagara Falls, N. Y., was selected as the place for holding the next annual meeting.

The Treatment of Gallstones Found as a Coincidence in Abdominal or Pelvic Operations.

Dr. John G. Clark, Philadelphia, called this an unsettled question. He removes such gallstones if the patient's condition permits. In his cases no death has occurred, nor had there been any serious complication referable to the secondary operation. He gave the history of 12 cases.

DISCUSSION.

Dr. R. Stansbury Sutton, Pittsburg, agreed that gallstones encountered during another operation should be removed, if the patient's condition warranted it. He said that kolalin obviated the necessity of operation in many cases. He had used it in dozens of cases in which he had held operation in abeyance, and did not have to operate subsequently.

Dr. George M. Edebohls, New York City, narrated a case in which he found a gallstone four centimeters long, while operating for movable kidney and appendicitis. The attending physician would not let him remove the stone. A year later operation for some other condition showed that the stone either had passed or had been dissolved. Treatment had been olive oil for about a month; whether this had anything to do with the passage of the stone he did not know.

Drs. Brooks H. Wells, New York City, and Seth C. Gordon, Portland, Maine, use practically the same measures as Dr. Clark. Dr. Wells said that in a number of patients complaining of obscure symptoms of so-called functional indigestion, cleaning out the gall bladder and draining it gave remarkable relief.

Dr. Hiram N. Vineberg, New York City, said that he had formerly done as had the essayist, but after hearing Dr. Mayo's views he had changed his method. Simply opening the gall bladder and removing the stones did not effect a cure, as was proved by three or four cases that occurred in his own practice. If the gall bladder was diseased, however, it should be removed.

Dr. J. M. Baldy, Philadelphia, said that gallstones existed for years without causing any material discomfort, but that when infection occurred trouble was liable to ensue.

Dr. Walter P. Manton, Detroit, quoted Ochsner as saying that he had tried almost everything in so-called cases of chronic dyspepsia without affording relief; yet after removing gallstones which were found, the patients were cured. Dr. Manton had seen a number of such cases, and contended for the removal of gallstones or the gall bladder if diseased. He did not believe that anything could be taken to dissolve gallstones.

Dr. Beverly MacMonagle, San Francisco, agreed that during operation for other cause, the operator should investigate the gall bladder. If the surgeon could do something of a prophylactic nature, without adding to risk of life, it was a wise thing to do.

Ovarian Pregnancy.

Dr. J. Clarence Webster, Chicago, reported a case. There was a right ovarian irregularly rounded swelling, measuring 7 by 8 centimeters. There was no evidence of rupture into the peritoneal cavity. The adhesions were recent. Sections of the ovarian swelling consisted mainly of extravasated blood and disseminated fragments of the chorion. No evidence of transformation of ovarian connective tissue into decidual was noted. It was certain that the pregnancy did not start in a graafian follicle.

DISCUSSION.

Dr. J. Whitridge Williams, Baltimore, said ovarian pregnancy was the rarest of all forms of extrauterine pregnancy. While there was no doubt that muellerian tissue might be found in the ovary, as mentioned by the essayist, and confirmed by numerous observers, it was going too far to advance that view in explanation of every case of ovarian pregnancy.

Dr. John T. Thompson, Portland, Me., and **Dr. Edward P. Davis**, Philadelphia, reported cases. In the latter's case the indications were that the pregnancy did not originate in the graafian follicle.

Dr. Lapthorn Smith, Montreal, had diagnosed ectopic pregnancy by the clinical symptoms, had operated, and found hematoma of the ovary. He had said to students that his diagnosis was wrong, because authorities maintained that there was no such thing as ovarian pregnancy, but after hearing what had been said he was convinced there was.

(To be continued.)

ILLINOIS STATE MEDICAL SOCIETY.

Fifty-fourth Annual Meeting, held at Bloomington, May 17-19, 1904.

(Concluded from page 1440.)

X-Ray Therapy.

Dr. Chas. D. Center, Quincy, gave a review of the cases reported to the society one year ago, with some additional notes used as illustrations. He pointed out the difficulty of telling before treatment whether benefit will follow the application of the *x* rays or not. He reiterated that more is claimed for the rays therapeutically than is justified, saying that this claim arises from some apparently brilliant results which are not supported clinically by the lapse of time.

Anal Fissure.

Dr. J. Rawson Pennington, Chicago, discussed the office treatment of fissure in ano. After referring to the etiologic factors, the more important symptoms and the diagnosis, he considered the non-operative and operative treatment, and mentioned divulsion of the external sphincter without the use of the ordinary general or local anesthetic.

Pregnancy and Appendicitis.

Dr. Chas. B. Reed, Chicago, spoke of the reciprocal influence existing between the inflamed appendix and the fruit sac, and of the disastrous consequences for the gestation and the fetus. The mortality statistics of this condition were compared with those of other serious complications of pregnancy. The difficulties of diagnosis during pregnancy and the desirability of adopting a definite mode of procedure in these cases were emphasized.

Intestinal Obstruction.

Dr. J. F. Percy, Galesburg, reported a case. He insisted on early operation, and outlined the best methods of treatment before consent for operation is obtained. He pointed out the wisdom of temporizing operative methods in a case of intestinal obstruction where exhaustion is extreme.

Imperforate Hymen.

Dr. Charles B. Horrell, Galesburg, described a rather unique case of imperforate hymen in a fairly rugged, rather athletic girl of 16. She was a bicycle rider, and was healthy, one in whom naturally an imperforate hymen would not be suspected, but the patient suddenly exhibited an abdominal tumor the size of a six months' gravid uterus. Examination revealed imperforate hymen, and an incision released about two quarts of grumous black blood, with perfect relief. He said that although this condition is rare, it may occasionally be found.

Antenatal Pathology.

Dr. Charles E. Paddock, Chicago, stated that there is a fetal pathology which has for its etiology certain factors which could have been prevented. Every case of pregnancy should be considered as an abnormal condition, requiring the advice and attention of a physician. A neglect to do this often means injury to the fetus. The fetus suffers from a hereditary taint, notwithstanding the possibility of such a condition being known by the physician and one or both parents.

Porro Operation.

Dr. Carl Wagner, Chicago, described a modification which consists in reversing the course of the operation. He described a method of controlling hemorrhage, pointed out the indications for the operation, and reported three cases, with recoveries.

Symphysiotomy in Persistent Mento-Posterior Face Presentation.

Dr. E. B. Montgomery, Quincy, reported a case. He had been unable to find much literature on the use of symphysiotomy in such cases, although all the text books on obstetrics are favorable to its performance. In his own case, the mother lived, but the child perished from asphyxia shortly after birth.

Hernia.

Dr. E. Wyllys Andrews, Chicago, exhibited a model for illustrating herniotomy and suture work on the abdominal parietes. He emphasized the importance of suturing abdominal wounds layer by layer, and pointed out the difficulty of showing all steps of the closure to large audiences. Students get inadequate notions of the real care necessary. Herniotomy can hardly be shown to more than eight or ten observers. He spoke of the value of cloth in layers to imitate abdominal fascia. The parts are almost perfectly reproduced in large size. The author's radical cure for hernia was demonstrated.

Immediate Abdominal Section.

Dr. Denslow Lewis, Chicago, in a paper with this title, said that the opinion is concurred in that increased facilities for surgical work and the multiplicity of hospitals in country districts often induced practitioners to undertake important abdominal operations without proper qualification or adequate experience. It is conceded that the usual post-graduate instruction may be a means of advertisement for the instructor rather than an honest attempt to teach the student-practitioner the details of operative technic. It is also admitted that many of those in attendance for a few weeks at post-graduate schools only too often seek a superficial knowledge of recent advances, and a respite from their everyday work, and few are actuated by a sincere desire to add to their actual surgical capability. Nevertheless, it is urged that under certain conditions abdominal section must be undertaken by the practitioner in charge, for without such intervention the patient's life is jeopardized, and in some instances the result is inevitably fatal. The principles of asepsis are simple and easily applied anywhere. The author cited cases from his recent experience in ectopic gestation, appendicitis, obstruction of the bowels, and other conditions where the demonstration has been made that immediate operation alone can save life.

Drainage.

Dr. J. N. Stealy, Freeport, discussed the use and abuse of drainage. The purposes of drainage were set forth, also the indications and advantages, as against the disadvantages and bad results of drainage. The author believes that in the present day the inclination is for less drainage.

Other Papers Presented.

In the section on practice of medicine, there was a very valuable symposium presented by Chicago physicians on tuberculosis.

Dr. George W. Webster spoke of the mortality of the disease in Illinois for the years 1902 and 1903.

Dr. Charles L. Mix pointed out the factors causing tuberculosis and aiding its spread. He offered suggestions for its prevention.

Dr. Frank Billings discussed the diagnosis of pulmonary tuberculosis, Dr. Robert B. Preble the treatment. Dr. Homer M. Thomas pointed out the annual economic loss to the state of Illinois from this disease. Dr. Harold N. Moyer discussed the duty of the state in restricting tuberculosis.

In the section on surgery there were symposia on eclampsia and carcinoma.

Dr. Palmer Findley, Chicago, spoke of the value of systematic blood examinations in gynecology.

Dr. Albert Goldspohn, Chicago, pointed out the reasons why digital exploration through the internal inguinal rings should be made in conjunction with every Alexander operation.

Dr. Geo. W. Newton, Chicago, spoke on cystic tumors of the ovary, and emphasized, by the citation of illustrative cases, the importance of early and correct diagnoses. He likewise spoke of the accidents to and changes in ovarian cysts.

Dr. Henry F. Lewis, Chicago, discussed some practical points in the diagnosis and treatment of placenta previa.

Dr. S. C. Stremmel, McComb, read a paper in which he made a plea for early and interval operations in cases of appendicitis. He presented some interesting statistics.

Dr. H. W. Chapman, Whitehall, reported a case of mastoid operation which embraced some unusual features.

Dr. R. R. Campbell, Chicago, considered the differential diagnosis between pseudo-membranous angina of syphilis and angina of diphtheria. He pointed out the difficulties encountered, referred to the treatment, and the results.

Dr. Thomas H. Bath, Bloomington, read a paper in which he brought forward successive scientific data confirming the mosquito as the definite host of malarial fever.

Dr. James Moreau Brown, Chicago, presented a general consideration of speech disorders, laying particular stress on etiology and treatment, and then discussed the so-called stammering institutes. He gave reasons why cases of this character should be treated by the physician.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Fissures of Nipples.

For the painful fissures or slits or clefts of the nipples the following combinations are of service:

℞.	Ichthyol	ʒii	8
	Glycerini	ʒiii	12
	Lanolini	ʒv	20

M. Sig.: Apply freely after nursing, and remove before the next morning by thorough washing; or:

℞.	Glycerini	ʒv	20
	Vitelli ovi	ʒiv	15
	Balsami Peru	gr. xlv	3

M. Sig.: Apply externally; or:

℞.	Balsami Peru.		
	Sodii boratis, āā	gr. lxxv	5
	Vitelli ovi	gr. xv	1
	Olei amygdalæ exp. q. s. ad	℥i	30

M. Sig.: For external application.

℞.	Tr. benzoini co.	gtt. xv	1
	Olei olivæ	ʒii	8
	Lanolini	ʒvi	24

M. Sig.: To be applied locally.

Seborrhea.

In the treatment of seborrhea, Shoemaker, in the *Internat. Med. An.*, recommends that attention be given to the anemia, digestive and menstrual disturbances which may be present. Locally galvanism is advised and bathing of the face every night with water as hot as can be borne. The following ointment is recommended:

℞.	Acidi salicylici	gr. xx	1	30
	Olei eucalypti	m. v		30
	Chloralis	gr. x		65
	Ung. zinci			
	Ung. aq. rosæ, āā	℥ss	15	

M. Ft. unguentum. Sig.: Apply locally after bathing the face in hot water, gradually increasing the salicylic acid to one dram (4.00) and the oil of eucalyptus to fifteen minims (1.00).

Dysphagia of the Acute Anginas.

Regin, in *Prog. Médical*, recommends the following combination to be insufflated into the throat for the relief of pain in acute angina:

℞.	Pulv. acidi borici			
	Pulv. lactose, āā	gr. xxx	2	
	Orthoformi	gr. xv	1	
	Pulv. talci	gr. xxx	2	
	Cocainæ hydrochlor.	gr. ¾		05
	Pulv. menthol	gr. 1/3		02

M. Ft. pulvis. Sig.: A small amount to be used as an insufflation into the patient's throat through a tube during inspiration just before taking food.

Treatment of Thrush.

Dr. Merletti, in *Jour. de Méd. de Paris*, recommends that successive applications of hydrogen dioxid and sodium borate be employed in the treatment of thrush. These two medicinal agents produce an abundance of froth which acts immediately on the organism present. This treatment should be repeated three or four times in twenty-four hours, and if begun early will destroy the fungus growth within the first twenty-four hours. It is of service even in the confluent type.

Olive Oil.

Harvey, in an abstract in *St. Louis Courier of Medicine*, considers pure olive oil Nature's best fat for dietetic purposes. It contains nitrogen and carbon, together with metabolic elements, oxygen and hydrogen in proper proportion to sustain life. Besides its value, which has been spoken of in the treatment of dysentery, the author recommends it in general ulceration and irritation of the stomach and bowels of alcoholics, in doses of half an ounce to an ounce (15.-30.) three or four times a day. In chronic constipation, in gallstones and jaundice, the author regards it as curative in many instances, as it seems to liquefy the cholesterin, preventing the formation of gallstones; it lubricates the bowel and promotes the flow of bile, thereby aiding digestion and regulating peristalsis. In nursing mothers whose milk is deficient in fats the pure oil emulsified and combined with the hypophosphites has been found to be of great advantage for both mother and child. He prefers this emulsion to all the fish emulsions, linseed or petroleum oils in the treatment of marasmus, rachitis, pulmonary or tubercular troubles and of benefit where a real food or tonic is indicated. It is also of value in the treatment of hyperacidity, chronic gastric catarrh and constipation.

Pruritus.

The following combinations are recommended by *Med. Record* in the treatment of general pruritus:

℞.	Acidi acetici	gr. xx	1	30
	Lanolini	ʒi	4	
	Liq. petrolati	ʒiii	12	

M. Sig.: Apply locally night and morning; or:

℞.	Acidi acetici	gr. xx	1	30
	Lanolini	ʒii	8	
	Liq. petrolati			
	Pulv. amyli, āā	ʒiii	12	

M. Ft. unguentum. Sig.: Apply locally.

Fissure Ani.

The most common cause of fissure of the anus, so states Bjorkmann in *Merck's Archives*, is constipation. Syphilis and hemorrhoids also favor their formation. The small fissure, as a rule, can be easily cured by the application of a 2 per cent. argentin solution or of the silver nitrate stick. In more stubborn cases the sphincter should be mechanically distended to relaxation, or better still, the fissure liberally incised, touched with the paquelin cautery and dressed with nosophen gauze. As a palliative ointment the following combination is recommended:

℞.	Beta-eucainæ			
	Menthol, āā	gr. xv	1	
	Ext. belladonnæ	gr. x		65
	Lanolini q. s. ad	℥i	30	

M. Sig.: Apply freely three times a day.

Treatment of Chancroid.

Dr. C. G. Clark, in an abstract in *Critic and Guide*, states that the first thing to do in the treatment of chancroid is to thoroughly disinfect the lesion and to wash the parts well with green soap and water, followed by alcohol or ether, and then thoroughly cleanse the sores with a bichlorid solution 1-2000. The penis must then be wrapped in gauze saturated with the above solution, which is kept moistened for twelve hours. The gauze is then removed, the sores dried and dusted with aristol. After this treatment the sores should be washed with a 1-5,000 bichlorid solution every three or four hours, dried and a fresh application of aristol made.

Complications must be guarded against; one of these is phimosis or paraphimosis. This should be relieved by slitting up the dorsum and laying the glans bare. The rest of the operation for circumcision may be done later, care being taken that the cut surfaces do not become infected by keeping them covered with the antiseptic powder.

In hard chancres the author follows out practically the same line of treatment, except he uses as a dressing equal parts of aristol and calomel. He strongly objects to the usual custom of cauterizing every venereal sore, believing that cauterization delays the process of healing and frequently leaves an ugly scar.

Medicolegal.

Family Physician Not Hearing of Mental Infirmity.—The Court of Appeals of Maryland says, in Watts vs. State, where the former was convicted of murder and an exception was taken to a ruling allowing his family physician to state that he never heard any intimation that he (Watts) was not mentally sound, that there was no evidence that the physician had ever attended Watts himself, or had occasion to question his sanity. Suspicions of this nature, if entertained by relatives, are often sedulously concealed from friends and from the physician of the family; and the court does not think that the mere fact that an attending family physician had never heard of any such infirmity should be admitted, to the possible prejudice of the defendant.

Statements to Physician as to Subjective Symptoms.—The Supreme Court of Wisconsin says, in the personal injury case of Kath vs. Wisconsin Central Railway Co. that in Keller vs. Gilman, 93 Wis. 9, there was an attempt made to formulate the rules governing the admission and rejection of evidence as to subjective symptoms of a patient in a way which should cover all cases. The present case shows how futile the attempt was. It was there said that such statements may be given in evidence when made to a physician for the purpose of treatment, but may not when made to an expert after action brought, in order to enable him to testify as a witness on the trial. This seems clear enough until a case is presented like the present, where the statements are made both for the bona fide purpose of treatment and to enable the physician to testify as an expert on the trial. On principle, the court thinks such testimony should not be admitted. It seems to it to be equally as objectionable as the evidence of subjective symptoms made to a physician for the sole purpose of enabling him to testify as an expert. Whenever such statements are merely narrative and not part of the *res gestae* (essential circumstances of a transaction), their relation on the witness stand is purely hearsay testimony. The rule which admits them when made in good faith before action, solely for the purpose of treatment, is an exception to the general rule excluding hearsay testimony. The exception is evidently based on the idea that there can be no reasonable probability that such statements are made with any self-serving purpose; that there is every reason to believe that they are true, because it would be absurd, not to say stupid, for a patient to make false statements to a physician who is to treat the disease, and who must base his treatment in part on such statements. While there is not that strong probability of truth which is held to make admissible a statement made on the threshold of impending death, there is some similarity in the two cases, in this: that the circumstances seem in each case to negative the idea that testimony would be manufactured, and, on the other hand, to indicate that there would be every inducement to state the truth. It is evident that this condition only exists where the patient seeks a physician for the sole purpose of obtaining treatment before litigation is begun or threatened. If he joins with that purpose an intention to call the physician as an expert on the trial of his case, whether then pending or to be commenced, then there is distinctly present the temptation to manufacture testimony when stating his symptoms and feelings to the physician. An easy way is thus opened to put any quantity of self-serving *ex parte* (from, or on one side) statements before the jury, by simply employing an expert to give a few days' treatment to the patient, and then putting the expert on the stand in his dual capacity of expert and attending physician. The case of Cleveland, etc., Ry. vs. Newell, 104 Ind. 264, was cited in support of the admission of the evidence in question in this case, and the Supreme Court of Wisconsin states that it was fair to say that it seemed to do so; but, it adds, the reasoning is not satisfactory to it, and it holds that evidence of declarations made by a patient to a physician after action is brought or threatened is inadmissible, where it is proposed to call the physician as an expert, notwithstanding that the patient may at the same time, in good faith, be seeking and receiving medical treatment. As touching a minor question in the case, the court holds that the rule is that an expert medical witness can not state what he learns entirely from medical works, unsupported by practical experience of his own, but the rule goes no further.

Duty of City Physician to Care for Smallpox Patients—Compensation.—The Supreme Court of New Hampshire says, in the case of Congdon vs. City of Nashua, that for all the time during which the services were rendered in caring for smallpox patients for which the plaintiff claimed payment under alleged contracts with the board of health elected by the city councils he held the office of city physician, and received the salary attached to the office in full payment for all his services as such physician. The ordinance creating the office of city physician made it his duty "to attend, under the general direction of the overseers of the poor, on all sick paupers, and patients under the care of the city authorities." The powers vested in the board of health of towns are by general law and by the charter of the city vested in the city councils, to "be carried into execution in such manner, by such officers, and with such powers as the city councils shall determine." It was the duty of the city to care for the persons confined, for the protection of the public, because of their affliction with a contagious disease, whenever such assistance was deemed wise or necessary by the board of health. Such persons were, therefore, "patients under the care of the city authorities," on whom the plaintiff, as city physician, was bound to attend. That this duty was to be performed under the general direction of the overseers of the poor did not limit the plaintiff's duty as city physician. The language of the ordinance defining his duty expressly implied that he was to attend on others than paupers, and, under the general statute, the city councils had power to commit the execution of a portion of the power vested in them as a board of health with reference to contagious diseases to the overseers of the poor and a city physician. If not paupers, the inmates of the smallpox hospital were patients under the care of the city authorities. Paupers and other patients afflicted with a contagious disease were not excepted from the class for which the physician was required to furnish medical attendance. The purpose of the ordinance creating the office of city physician, and prescribing his duties, was to provide such medical attendance as the city was legally liable to furnish. If the board of health had power to contract in behalf of the city for medical attendance on persons in quarantine, in case the city physician was unable, unwilling, or incompetent to furnish such attendance as was required, they had no authority to raise the salary of the city physician, or to bind the city to pay him more than the sum for which, by accepting the office, he agreed to perform its duties. In the absence of information as to the powers conferred on boards of health or health officers, it would be assumed that by the election of officers with such titles the city councils had expressly or impliedly invested them with the powers of like officers in towns. In Nashua the duties of the board of health officers are the same in substance as those of health officers or boards of health in towns for the prevention and removal of nuisances, with the exception that the execution of the power to make regulations is retained by the city councils, and the duty of the health officers is confined to carrying into execution ordinances and rules on the subject made by the councils. No power as to contagious diseases, such as is vested in health officers under the statute, appears to have been confided to the health officers of Nashua. If there was evidence not disclosed by the case from which it could be inferred that it was intended to intrust to them the execution of the power of quarantine, the fact that the city councils had provided another officer to supply the necessary medical attendance established that the furnishing of such attendance was not committed to the health officers. There being nothing in the case tending to show that the health officers had been authorized to furnish medical attendance at the expense of the city to persons in quarantine, they could not make a valid contract with a third person for that purpose. However, although the plaintiff's contract as city physician was to perform the service for the salary, it was within the power of the city councils to give or agree to give him additional compensation for service more onerous than was anticipated.

2. *The Relation of the X-Rays and Radio-Active Solutions to Examination of the Stomach. Sinclair Tousey.
3. Treatment following the Bloodless Reduction of Congenital Hip Dislocation. Dexter D. Ashley and Frederich Mueller.
4. *An Operation to Reach the Lower Ureter by an Extraperitoneal Route. T. C. Witherspoon.
5. *Vasomotor Center in Inhibition of the Heart (Concluded). Charles E. DeM. Sajous.
6. Case of Diabetes Millitus; Gangrene of the Foot; Operation: Recovery. E. P. Stone.

2. **Stomach Examinations.**—Tousey gives the results of his observations with radioactive solutions and the *x*-rays in the examination of the stomach, illustrating some of his experiments. He finds that the radio-active and fluorescent solutions as prepared by him with quinin bisulphate and fluorescin, are innocuous when given by the mouth or subcutaneously, but do not produce singly, or in combination, sufficient fluorescence to be of value in the examination of the stomach without the use of some additional light to excite their fluorescence. They will, however, in some cases be of the greatest assistance in the diagnosis of stomach lesions, and in some cases be of advantage in the *x*-ray treatment.

4. **The Extraperitoneal Route to the Ureter.**—This method, adopted by Witherspoon, consists in an incision four inches long near the lower end of the rectus, extending upward from its insertion, parallel with its fibers. Then the muscle is divided longitudinally by blunt dissection through the middle and the fascia below the semilunar fold of Douglas being divided, the peritoneum and its fatty layer come into view. The lower ureter is then exposed extraperitoneally in the following way: The bladder and its fatty covering in the portion of the wound are pushed upward and inward, and the peritoneum separated from the abdominal wall as far as the iliopectineal line. The index finger then enters the pelvis at the side of the bladder, pushing upward and inward the fold of peritoneum known as the lateral false ligament of the bladder. After passing the finger well down to the base of the bladder, the separation of the peritoneum from the pelvic wall is carried posteriorly as far as the vas deferens. The fascia here is loose. The vas deferens is a good dividing line for the pelvis, as passing down on its outer wall it lies midway between the symphysis and the center of the sacrum. He describes its course here, and shows how it passes inward over the obturator and recto-vesical fascia to the posterior wall of the bladder passing above the ureter. Where a ureteral catheter has been introduced or a stone has lodged in the lower ureter, there will be no difficulty in locating it. Where these do not exist, it becomes necessary to have some guide. If the vas deferens is followed about two inches onward from the point of crossing the obturator vessels the ureter will be found just behind it. This point is from three-fourths to one inch from the point where the vas deferens turns inward to the bladder. The vas deferens and ureter are both raised with the peritoneum when dissection is made. The ureter is freed from the delicate fibers which bind it to the peritoneum and is brought clearly into view. Some three or four inches may be examined, and the index finger can follow it to the brim of the pelvis. He points out the relation of the obliterated hypogastric artery to the operation. The advantages are: 1. It is extraperitoneal, and avoids the danger of peritoneal infection. 2. The opening is directly over the route of the ureter, and offers a good view of that organ through the small cut. 3. It allows of thorough palpation through the peritoneum, of both kidneys and ureters, and an exposure of the ureter on the side of the incision for extraperitoneal operation on its lower end. In many cases thorough palpation may be desirable. 4. There is a bloodless field of operation, and no forceps are in the way. 5. Drainage is usually necessary after opening the ureter, which may be carried through the lower end of the rectus, and does not leave the prospect of hernia that a para-Poupart incision does. 6. Dissection is not difficult, and may be carried out by any reasonably prepared surgeon. In conclusion, he enumerates the methods proposed for operation on the ureter.

5. **The Vasomotor Center in Cardiac Inhibition.**—Sajous, in the conclusion of his paper, says that really no cardiac inhibitory apparatus exists as a physiologic entity. The life of the cardiac muscle is perpetuated by the action of the vasomotor centers, and vaso-constriction causes abeyance of the functions of the organ.

7. *Study of 91 Operations for the Relief of Various Forms of Hernia, with their Complicatioons. Orville Horwitz.
8. *Malposition of the Head (Torticollis, Canted or Tilted Head), with Resulting Ill-health, Spinal Curvature, etc., Due to Eyestrain. George M. Gould.
9. *Some Facts Concerning Radium and the Use of the Intragastric Radiode. J. A. Storck.
10. *Treatment of Pneumonia. R. S. Thornton.
11. Preliminary Report of a Case of Splenomyelogenous Leukemia Showing Marked Improvement Under the Use of the Roentgen Ray. Charles H. Weber.
12. *The Therapy of Acetanilid. J. R. Johns.
13. The Medical Inspection of Schools. Helen MacMurchy.

7. **Hernia.**—From a study of the cases discussed, the following conclusions, seem to Horwitz, to be warranted:

1. The safety of the patient as well as the lowering of the mortality in strangulated hernia depends on gentle taxis being exerted for a short period, which, if unsuccessful, should be succeeded by an immediate operation.
2. Herniotomy for the relief of strangulated hernia in the aged is not a dangerous operation, provided it is performed as soon after the constriction has taken place as possible.
3. An inflamed hernia should not be treated by taxis, but should be subjected to an operation.
4. No one method of attempted radical cure is applicable to every variety of rupture. The Bassini is suitable to the largest majority. The Bloodgood for those in whom a large abdominal ring and weak or atrophied conjoined tendons exist. The relief of special forms and conditions of hernia must be met by the ingenuity of the surgeon, selecting the operation to the indications presented.
5. The palliative operation is applicable to a large number of selected cases of reducible hernia, in which the protrusion can not be kept within the abdominal cavity by means of a truss, and also in some forms of incarcerated hernia.
6. A radical cure may be safely attempted on patients who have reached their sixth year and on those who have arrived at their sixtieth year.
7. Individuals who submit to what is known as the "palliative operation," should continue to wear trusses after recovery.
8. In cases not applicable to a routine method of operation, the surgeon should strive to do what, in his judgment, would be the best means of effecting the removal of the entire neck of the sac on a level with the parietal peritoneum; he should, if possible, firmly close the opening in the peritoneum after the removal of the sac; he should obliterate the depression of the peritoneum in the vicinity of the internal abdominal ring, bring in apposition the structures, and close the apertures which form the canal through which the rupture protrudes.
9. An aseptic result following a radical operation, with primary union, is essential to obtain a permanent cure of hernia.
10. In cases of undescended testicle associated with hernia, every effort should be made to save and transplant the organ.
11. The method of operating for umbilical hernia suggested by Mayo is probably the most satisfactory for that variety hitherto suggested.
12. Absorbable sutures are preferable to those of non-absorbable material.

8. **Malposition of Head, Spinal Curvature, etc., from Eyestrain.**—Gould calls attention to this cause of torticollis and spinal curvature, and gives his method of examination. He makes the patient sit erect, head upright, facing the test-letters in such a position that any abnormality in position may be quickly observed. If the patient's head remains or returns to any abnormal inclined, twisted position, the question is

whether he is right-handed and right-eyed. If so, the axis of astigmatism causing the malposition of the head is probably in the right eye, and vice versa. All astigmatism that can produce head-canting must be from 8 to 25 degrees, usually 10 to 18—to either side of the axis 90 or 180. If the tilt of the head is dextrad, the axis of astigmatism of the dominant eye is in the neighborhood of 75 or 165 degrees. If hyperopic, in the great majority it will be about 75; if myopic, the larger figure. If it is sinistrad, the axis of the dominant eye will usually be about 105, rarely 15. If the head is thrown directly backward or forward in a stiff and constrained position, it is probably due to hyperphoria, and the effort to bring the two visual axes to a horizontal. In most cases the tilt is toward the right, because most young people are right-handed and right-eyed and hyperopic. The number of patients with this defect is astonishing, and the number of those with secondary and unsuspected abnormally curved spines is not less remarkable, though this may not be discovered until it is revealed by examination. He reports briefly several cases and thinks that the suggestiveness of the ocular cause of the head and spinal deviations will probably throw much light on other obscure problems of ophthalmology, neurology, etc. One can foresee how it may be one of the causes of heterophoria of all kinds, especially cyclophoria, and of a number of chronic and inflammatory conditions of the fundus, of strange reflex ocular neuroses, etc., and explain many failures to cure migraine, hysteria, neurasthenia and other reflex neuroses.

9. **Radium.**—The intragastric "radiode" consists of an aluminum capsule containing 10 mg. of 7,000 radio-active radium, attached to a flexible copper wire passed through a suitable rubber tube, the capsule being allowed to project beyond the end of the tube, manipulated so as to come as near as possible in contact with the growth in the stomach. Storck has had experience with it in only one case, but it has not been very successful, though the patient thinks he eats better.

10. **Treatment of Pneumonia.**—Thornton insists on a trained nurse if possible, an equable temperature of 65 to 70, good ventilation, moist atmosphere perhaps medicated with some soothing substance, concentrated and nourishing food. Poultices he would reject, or if used at all, they should not be continued beyond the congestive stage; a smart mustard plaster retained until the skin is thoroughly reddened and then a cotton jacket and hot-water bottle, if continuous heat is desirable, will give just as satisfactory results. The general constitutional treatment must be that of a toxemia; keeping the bowels and kidneys active, the allaying of pain, restlessness, sleeplessness, etc., for which he advocates codein, and he would use aconitin to quiet the circulation and reduce the temperature. In medicinal doses it does not depress the heart. Digitalis and strychnia are especially valuable near and after the time of crisis, and he pleads for the use of these active principles rather than the uncertain galenic preparations. As regards alcohol, he does not employ it at all. Strychnin and digitalin have a better permanent effect, and in cases of collapse, atropin is greatly preferable. Of late years the method of treatment by the use of creosote or creosote carbonate has given good results, and the evidence in favor of its beneficial action in pneumonia is accumulating. The average adult dose of carbonate or creosote is 10 m. or 0.6 c.c. every three hours. The value of the treatment is proportionate to the earliness of its adoption. He does not speak well of any organic treatment of pneumonia so far as our present experience of it goes, but reports briefly a bad case cured under the methods above described.

12. **Acetanilid.**—Johns thinks acetanilid is deserving of a more extended use, and it has generally been given in too large doses. It does not need to be given in as large a dose as antipyrin. The dose may be said to range from 2 to 8 grains with a maximum for twenty-four hours of about 30 grains. Only exceptionally and in well-selected cases, is a dose of 10 grains advisable. Acetanilid expends itself in the domain of the sympathetic nervous system, and is particularly inimical to morbid reflexes in the sensory sphere. Small doses, 1 to 2 grains, produce a sense of ease and quiet within without a feeling of depression. It is primarily an analgesic. Its action in fever is on the sympathetic nervous system; the result of this action is an absolute loss in the production of heat and reduction of metabolism, though they can not fully account for the antipyretic action. Summing up, the effects on the nervous system are sedative, analgesic, antipyretic, antispasmodic and antiperiodic. In addition to being beneficially palliative, these effects are, in a large measure also curative. It is our best remedy for the relief of pain not due to local inflammation, such as reflex pain, etc. It is a valuable adjunct to other remedies as a modifier of action, such as quinin, salicylates, opium and calomel. In the last fifteen years he finds that the effect of giving acetanilid with quinin was more pleasant to the patient and better results from a larger quantity of acetanilid and a smaller quantity of quinin. In addition to the modifying effects on the main remedy, we have the analgesic and antipyretic effects so essential in the treatment of rheumatism. It is antagonistic to opium in some respects; supplementary in others. It takes the soporific influence from opium. It relieves without the resulting drowsiness and sleep. It is of value in combination with calomel in the treatment of many acute and subacute maladies in children. He knows no condition, he says, where a small dose of calomel with or without sodium bicarbonate is indicated where acetanilid could not be advantageously added. In doses of one-half grain, it is a good substitute for the Dover powder formerly used. Treatment with calomel and acentanilid in small doses every hour, followed by a mild purgative in intestinal troubles, affords early relief and makes for a speedy cure. He says when the indications for treatment are not clear and you do not know what to do, give acetanilid. It won't mask the diagnosis or interfere with the inauguration of any other course of treatment. When only psychic features of the case demand drug treatment, give it in two-grain doses. It is harmless as any placebo, and may be relied on to have a favorable mental effect.

14. *Treatment of Pneumonia. Jose M. Ferrer.
15. *Renal Redecapsulation. George M. Edebohls.
16. *Operative Surgery Applied to the Seminal Vesicles; a Demonstration of Some New Principles. Eugene Fuller.
17. *Who is Underfed? Heinrich Stern.
18. Tetanus Treated by Intraneural Injection of Antitoxin. John Rogers, Jr.
19. Multiple Gonorrheal Periarthritis in a Child. Probably Due to Inoculation Through a Wound. Henry Heiman.

14. **Pneumonia.**—The remedies favored by Ferrer are quinin, digitalis and cardiac stimulants which seem to act well. He advises isolation, an equable temperature, relief of pain and vomiting, the judicious use of morphin to relieve irritability and insomnia when cyanosis and edema are not present, bromids in some cases, compound spirits of ether in cases of asthmatic tendency is occasionally useful, relief of tympanites by calomel and soda, colon irrigation, plenty of cold water by the mouth to relieve the fever, cold pack in cases of very high temperature, stimulants for the heart for which he uses alcohol, strychnin, etc., hypodermoclysis in some cases, rectal injections of normal salt solution and lastly a mixed liquid diet suited to the patient's inclinations and thorough ventilation are insisted on.

15. **Renal Redecapsulation.**—Edebohls reports a case where this was performed and maintains that the removal of the new capsule presents no greater technical difficulties than removal of the ordinary renal capsule.

16. **Surgery of the Seminal Vesicles.**—The method adopted by Fuller consists in seminal vesiculotomy or the exposure of the cavity of the seminal vesicles by means of a free longitudinal incision. Following this he uses drainage, curettage and removal of the intra-seminal vesicle neoplasms. Another feature which he has added to the above is freeing the organ through peripheral dissection of the surrounding inflammatory adhesions, a sort of decapsulation as it were. In his former article, published in THE JOURNAL of May 4, 1901, he reports his first five operations. In the present one he gives the results in 21 cases, which he divides into five groups. Group 1

consisted of extremely chronic cases of seminal vesiculitis, with lesions chiefly of sclerous tissue. Six of his operative cases were of this group. In 4 of them his results were good. In 2 the clinical results were negative. Group 2 consisted of cases of seminal vesiculitis, less chronic than those of Group 1. The intravesical catarrh was still a prominent feature, the sclerotic lesions not having fairly developed. Eight of his cases were of this character. Three out of the 8, however, are recent cases, just having been discharged from the hospital in a satisfactory condition. He expects good results; 3 of the other 5 he considers gave positively good results. Two cases were lost sight of too soon to be positive as to the results. Group 3 consists of cases of acute diffuse peri-seminal vesicle abscess of gonorrheal causation. Five cases come under this head. In all the results were particularly good. Groups 4 and 5 have one case each; the first, that of adenoma involving the wall and nearly causing the obliteration of the cavity. The result of the removal was good. In Group 5 the lesion was tuberculous involvement, and removal of the sac caused only temporary relief. A brief clinical recital of the individual cases follows. In conclusion, he states what he considers the advantages of this method, and advocates it in many cases of Group 1, some in Group 2 and all of Groups 3 and 4. For the liberation of pus in this deep region the operation under consideration is better than the three other surgical methods in vogue, namely, perineal section, incision through the rectal wall and perineal incision through the prostate.

17. **Underfeeding.**—Stern maintains that we generally eat too much. The animal functions, the tonicity of the structure and the organs and the normal intrasystemic equilibrium are better maintained, the more the sum of ingested assimilable nutrients is limited to the amount absolutely necessary to keep the body in metabolic balance. A diet of 35 to 50 calories for each kilo of weight, the usual standard of to-day, is too much. He thinks a lower figure for the majority of cases ample, and a small body weight is not necessarily an indication of underfeeding or one requiring overfeeding.

20. *Lesions Peculiar to the Pancreas and Their Clinical Aspect. Eugene L. Opie.
21. *Prophylaxis and Medical Treatment of Diseases of the Pancreas. Glentworth R. Butler.
22. Classification and Symptomatoloogy of Diseases of the Pancreas. Charles G. Stockton.
23. *Renal Decapsulation from the Pathologist's Point of View. Joshua M. Van Cott.
24. Cancer of the Intestine. J. G. Sherrill.
25. Fracture of the Base of the Skull as a Cause of Epilepsy; Report of Case. Charles J. Aldrich.

20. **Pancreatic Lesions.**—Opie's paper is a general review of the pancreas and its lesions so far as we know them. He begins with a few general anatomic and physiologic data, and calls attention to the characteristic lesion from pancreatic secretion in other tissues, namely, fat necrosis, which often serves as an index to pancreatic disease; describes acute hemorrhagic pancreatitis, which may carry a person off within forty-eight hours, and its association with gallstones, though as compared with cholelithiasis it is a rare disorder. What is said as regards acute hemorrhagic pancreatitis is applied, with some modifications, to the condition known as gangrenous pancreatitis, which is a secondary stage of the hemorrhagic lesion. It is usually associated with suppuration limited to the lesser peritoneal cavity, and its treatment is that of localized peritoneal abscess. Other conditions, such as obstruction of the ducts and the relation of the pancreas to carbohydrate metabolism, are noted at some length, especially the connection of pancreatic lesions with diabetes when the islands of Langerhans are involved. He thinks the relation of diabetes mellitus to lesions of the pancreas explains the frequent association of diabetes with other diseases, such as cirrhosis of the liver and the remarkable condition known as bronzed diabetes, is an excellent illustration of the coexistence of cirrhosis and chronic pancreatitis. Opie holds that when diabetes is found in an individual suffering with cirrhosis of the liver, the former disease is dependent on the coexistence of chronic interacinar pancreatitis, doubtless produced by some etiologic factor—in some cases alcohol—which is responsible for the hepatic disease. In this case, at least, it is possible to make a diagnosis of *pancreatic diabetes*. Also when during life diabetes accompanies advanced arterial disease, it may with much probability be attributed to chronic interacinar pancreatitis. He does not, however, consider that our knowledge of the relation of the pancreas to diabetes can clear up the practical therapy of the condition. The results of organotherapy have not been so uniformly successful as to warrant expectation of more than some slight benefit.

21. **Prophylaxis of Pancreatic Disease.**—Butler considers that the appreciation of the causes of pancreatic disease is necessary for prophylaxis. Among them are syphilis, tuberculosis, arteriosclerosis, cardiac, pulmonary and renal disease, acute and chronic infections, obesity, non-pancreatic diabetes, neoplasms, catarrhal and bacterial disorders and affections of the liver and gall bladder, especially cholelithiasis. If these can be successfully treated the liability to pancreatic disease is lessened, as beyond this we can not go. With our present state of therapeutics, the medical treatment is confined to the relief of symptoms, pain or jaundice by the usual methods, and the maintenance of the strength of the patient by rest, feeding, etc. When the presence of pancreatic calculi is diagnosed, the injection of pilocarpin has been reported successful by Eichhorst. The practical results of pancreatic therapy have been disappointing, but where there is a lack of pancreatic juice, the use of efficient pancreatic preparations has, in some cases, improved the digestion of fats and proteids, and the internal use of oxgall has aided in the assimilation of fats.

23. **Renal Decapsulation from the Pathologist's Point of View.**—Van Cott discusses the anatomy and physiologic conditions of the kidney, and concludes that on teleologic grounds the renal circulation can not be restored by decapsulation and substitution of the capsula adiposa. No amount of restoration of the renal circulation would restore the integrity of the cortex. Chronic nephritis as a local expression of a general disease will yield only to such treatment as is calculated to cure the latter, and there can be hope of only arresting the progress of the renal degeneration. The degenerated portions will never regenerate. He reports experiments on cats to test these opinions, and the findings are in harmony with these conclusions.

Boston Medical and Surgical Journal.

May 19.

26. *Enterostomy in Peritonitis. Robert R. Greenough.
27. *A Comparative Study of the Death Rates for the State of Massachusetts for the Years 1850, 1875 and 1900. William F. Whitney.

26. **Enterostomy in Peritonitis.**—Greenough discusses the advantages of enterostomy together with its disadvantages, the method of performing the operation with the Mixter tube and sums up his points in the following:

1. The obstruction of the intestine in diffuse peritonitis is the result of a combination of causes.
2. The most important cause is suspension or paralysis of peristalsis.
3. Paralysis of peristalsis is due to inhibition, to toxic paralysis and to the paralysis of distention.
4. Mechanical causes, such as infiltration of the bowel wall and light adhesions in certain cases contribute to this paralysis.
5. Pure mechanical obstruction due to adhesions is the result of chronic or local peritonitis of at least some days' duration.
6. Enterostomy is indicated in addition to other operative measures in the graver forms of diffuse peritonitis.
7. Its greatest advantage is the drainage of the gases and decomposing contents of the bowel and the relief of paralysis of peristalsis.
8. By enterostomy the surgeon obtains direct control over the intestine for lavage and for the introduction of stimulants, nourishment, fluids and cathartics.
9. For the relief of paralysis of peristalsis primary enterostomy is to be preferred to the secondary operation.
10. Enterostomy is best performed by the use of the Mixter tube.
11. The cecum is the most satisfactory part of the bowel for a primary enterostomy, and the jejunum is to be avoided.
12. Spontaneous closure of the fistula may be expected when the cecum is opened, if the opening is kept below the level of the parietal peritoneum.
13. By the systematic use of enterostomy in the graver forms of diffuse peritonitis the number of patients dying on the second, third and fourth days after operation is reduced.
14. The symptoms of visible peristalsis and spasmodic pain in intestinal obstruction indicate a mechanical cause for the obstruction.
15. The persistence of these symptoms, unrelieved by enemata and cathartics, is an indication for operation.
16. Under these circumstances the cause of the obstruction should be removed if possible by operation.

17. In advanced cases of obstruction of this form enterostomy of the coil of intestine nearest above the obstruction should be done.

A long series of abstracts of cases closes the paper.

27. **Death Rates in Massachusetts.**—The death rates for three years, 1850, 1875 and 1900, separated by twenty-five year intervals, are compared by Whitney, who finds that the ratio in the earlier years was decidedly less than in the later ones, and that the rate for females was lower than that for males. The ratios for age were also increased in 1875 over 1850 and over thirty years of age also in 1900, though there was a decided drop in the earlier period of life up to thirty. The only comforting point, he says, is that during the last twenty-five years it has been apparently less than before. A more detailed study of the age period shows a marked decrease in 1900 over every period from 1 year to 50 for both sexes, but from that time to the end of life there is a distinct increase. It seems that the progress that has been made is greater in the early periods. Still the death rates for infants under one year is greater than in 1850. He suggests that the decline of maternal nursing of later years has something to do with this result. *Children that were born in 1850, according to his figures, had* a better chance of reaching the end of the first year, while from that time on infectious diseases claimed many victims, but those who reached the age of 50 could look more confidently forward to old age. In 1875 the new era of medicine had just begun with the passing of the quieter modes of living, the crowding in cities, the natural checks were broken down and the result was what might have been expected. At the present time, however, preventive medicine and hygiene have more than offset the evil effects of our concentrated, high-pressure civilization up to 50 years of age. After that science appears to be powerless against the diseases of old age.

28. *Electrothermic Hemostasis in Abdominal Surgery. W. H. Wenning.
29. *Some Guiding Principles of Ophthalmic Practice as Regards *a Few of the Common External Diseases of the Eye. Derrick T. Vall.*

28. **Electrothermic Hemostasis in Abdominal Surgery.**—Wenning points out the advantages of the thermic angiotribe devised by Downes. In the first place, an ideal asepsis; second, a gain of time; third, instead of a puckered-up bunch of tissue grasped in a ligature, we have a more or less narrow ribbon of perfectly smooth and clean membrane which does not disturb the relationship of the different parts and lessens the danger of adhesions; fourth, pain and shock are almost entirely obliterated. In his experience the absence of shock and freedom from pain after operation are most remarkable features in the after-treatment of cases. As regards the danger of secondary hemorrhage, he considers it nothing provided the instruments are in working order and are properly applied. Ten cases are reported of the use of this instrument with good results.

29. **Common External Diseases of the Eye.**—The disturbances noticed by Vail are abscess formation in the lids, hordeoli and acute chalazions calling for moist warm applications at repeated intervals. Blepharitis marginalis suggests hydrogen peroxid or warm sodium bicarbonate to dissolve the crusts along the free border of the lids. Nitrate of silver is dangerous in the patient's hands and should only be used by the surgeon. Acute conjunctivitis calls for the open treatment, by which he means the avoidance of bandages and assisting nature in ridding the eye of irritating influences by frequent bathing; cold applications, antiseptic drops and astringent applications to the everted lids, protective sun glasses, vaselin ointment and rest of the eyes from work assist in the milder cases. In desperate cases we should remember the dangers of too much edema of the lids and have recourse to leeching, light ice compresses and canthotomy. Abrasion of the cornea calls for the roller bandage, with recovery in a surprisingly short time if this is applied. It is well, however, to douche the conjunctival sac with *a warm solution of boric acid* so as to get rid of any loose irritating substance. The patient should not use cocain. Abrasions frequently heal in twenty-four hours without it. The bandage protects the eye, allows healing to go on, shuts out irritation, prevents infection by the patient's hand or handkerchief, etc. Foreign bodies in the cornea should be removed as soon as the proper instrument for their extraction is sterilized and cases treated for abrasion left as above. Phlyctenular keratitis generally implies some systemic derangement, as sometimes after fevers or with certain disturbances of digestion. The proper local treatment is to wipe off the blister after cocainizing the eye by means of a small bit of cotton wrapped rather tightly on a cotton carrier and dipped in boric solution. Insufflation of calomel powder after the blisters have ruptured or been swept off gives the best results, or if the bed of the ulcer has been deeply infected we may expect good results from the application of ½ per cent. silver nitrate solution to the everted lids followed by Y. O. ointment ½ per cent. The eye should not be bandaged and the patient kept in the house out of the sunshine. Good food and proper hygiene are as important as local treatment. Ulcer of the cornea is sometimes treated as above, but there is no certain way of killing off the bacteria except by the careful application of pure carbolic acid solution or the actual *cautery.*

32. *Treatment of the Early Stage of Pelvic Inflammation, with Some Points in Diagnosis. A. W. Abbott.
33 *The Early Diagnosis of Tuberculosis. W. H. Darling.

32. **Pelvic Inflammation.**—The conditions of early gonorrheal infection and inflammation are reviewed by Abbott, who thinks that a thorough understanding by the laity of the dangers of gonorrhea and abortion would make more secure the lives and happiness of thousands of women and do away with two-thirds of the work of the gynecologist. Septic pelvic infections are generally preventable. Prompt rational treatment based on a knowledge of the bacteriology of pelvic inflammation will save many lives and cut short much suffering. Early and efficient vaginal drainage when indicated will not increase the difficulties of subsequent radical operation, but will add to its safety and make a more conservative operation more feasible and perfect.

33. **Tuberculosis.**—Darling thinks that many of the symptoms formerly classed as early symptoms in diagnosis of tuberculosis really belong to the more advanced stages and that cough, expectoration and hemorrhage do not occur early in the disease. Emaciation and muscle weakness are the first constitutional symptoms in nearly 90 per cent. Harsh respiratory sounds are the earliest local symptoms in 95 per cent. Except for the early leucopenia and anemia pure tuberculosis has little effect on the blood and the diagnostic value of Koch's tuberculin, conservatively used, can not be overestimated. Bacteriologic diagnosis can only be made after there is disintegration of tubercles and free communication between the diseased area and the bronchus. When bacilli appear in the sputum the disease is in an active stage and there has been considerable breaking down of tissue. Treatment can then only be palliative. The hope of cure is small, but we can prevent the victim from being a source of danger to his associates.

35. *The Localization of the Placental Site. Edmond M. Lazard.
36. Lung and Intestinal Troubles in Young Children. Kate Wilde.
37. Some Impressions of European Accessory-Sinus and Ear Work. Ernest W. Fleming.

35. **The Placental Site.**—Lazard notes the lack of mention of localization of the site of the placenta in the usual text-books and journals, and gives the results of his experience during his service as externe under Leopold in Dresden in 1901. *Leopold, after noting the* peculiar relation of the course of the tubes to the placental site in some twenty cases of cesarean section, formulated the following rule: If the tubes converge upwards on the anterior uterine walls to the fundus, the site

of the placenta is the posterior uterine wall; if, however, the tubes assume an approximately parallel course along the sides of the uterus, the placenta is situated anteriorly. This is part of the routine in the Dresden Frauenklinik, noted in every obstetrical history. The diagnosis is made as follows: The round ligaments are palpated with the palmar surfaces of the index, middle and ring fingers, and are followed up to their insertions in the uterus, thus locating the tubal insertions. The course of the tubes are marked on the abdominal wall with a blue pencil. The tubes and ligaments are more readily felt by affecting a slight uterine contraction during the later months of pregnancy and are also more readily felt during a pain in labor. The left tube is more easily palpated; it is usually necessary to feel more posteriorly for the right. The explanation of the peculiarity as given is that the location of the placenta causes a bulging or broadening on the wall on which it is located at the expense of the opposite. In some fifty-eight cases where a diagnosis was made and there was a chance to verify it at cesarean section, there were only two where it failed and there special conditions existed. The advantages of a knowledge of the location of the placenta in cases of cesarean section, etc., are obvious. As regards placenta previa and its influence on the course of the tubes, Lazard is not able to speak positively. He thinks, however, that the placenta in the lower uterine segment would not affect the insertions and that the tubes would be approximately parallel along the side. The diagnosis of placenta previa, therefore, would not be helped by this method; it would have to be made otherwise.

40. **Tonsillitis and Rheumatism.**—Miller has had a number of cases of rheumatism preceded by tonsillitis in apparently causal relation and gives the opinions of Osler, Poynton, Paine, Menzer and others as to the etiologic relation of tonsillar inflammation to rheumatic disease. He thinks that whenever possible we should urge on the patient suffering with tonsillitis the necessity of care and careful attention to the directions laid down as to the care of the throat and that the salicylates should be given all through the attack and continued for one or two weeks after convalescence has begun; the necessity of a proper care of the body during convalescence and for a time afterward in regard to exposure, dampness and severe exertion should be insisted on.

46. **Chorea and Graves' Disease.**—Fry remarks that of late there have been some publications pointing out the existence of a relation between chorea and Graves' disease. The parallelism has been summed up by Sutherland in *Brain* for 1903, showing many points of resemblance. Fry calls attention to the fact that he published a case in *The Journal of Nervous and Mental Disease*, September, 1892, which so well illustrated the subject that he thinks it worth while to here offer a few quotations. The patient had a decided tremor with chorea and later developed all the symptoms of Graves' disease. He has also lately seen a case of marked exophthalmus with the usual syndrome of juvenile chorea in pronounced form in a boy of twelve. In his earlier paper he noted the fact that choreic movements were not alone adequate for the diagnosis and, in fact, that the prechoreic stage of the chorea has been described as chorea. The relative diagnosis of the value of the spasm on the one hand and other choreic symptoms on the other, he thinks, will have to be settled in each individual case.

65. Peripheral Neuritis. William Broaddus Pritchard.

49. **The Chlorid Reduction in Nephritis.**—Widal and Javal report a study carried out on a patient with nephritis in which the reduction of chlorids in the diet was regularly and systematically tried at intervals. The conclusions to which they come is that the best treatment for certain stages of the disorder is to lessen for a while the absorption of chlorids. Milk, which has been empirically found to be so valuable, owes its value largely to the lack of salt and experiments show that a diet can be found containing even less chlorids than milk. A variety of forms of solid food may be taken by themselves or in combination with milk, providing no salt is added, and may be an excellent aid in the treatment of nephritis by chlorid diminution.

50. **Adonidin.**—This is a glucosid from false hellebore (Adonis vernalis) and has been studied by Wilcox, who here gives his results with sphygmograph tracings. The remedy, he thinks, has a field of usefulness not entirely supplied by digitalis. This is in its promptitude of action and its freedom from cumulative effect. The objection to it is that it is irritating, which may prevent its long-continued use.

51. **Collargol.**—The history of this substance, its discovery by Carey Lea in 1889, and its introduction into medicine by Crede, is reviewed by Netter and Salomon, who speak of the usefulness of the remedy by intravenous injection as well as local treatment. They do not think the intravenous method dangerous, and say it should be resorted to in all cases that seem truly serious where the remedy is indicated, such as the majority of infectious diseases, pyemia and septicemia, generalized or attenuated puerperal infection, infectious endocarditis, cerebrospinal meningitis, severe scarlet fever, associated diphtheria, severe forms of typhoid, some types of tuberculosis with pneumonic tendency, pneumonia, bronchopneumonia, rheumatism with vicious tendencies, grippe, appendicitis, etc.

54. **Pneumonia.**—Davis considers that the modern treatment of pneumonia fails through the lack of active efforts to lessen pulmonary and cardiac congestion, reduce the fever and permit an early crisis by the old-fashioned methods of the use of venesection, tonics and the general so-called antiphlogistic and blood-letting treatment of pneumonia in favor during the first half of the nineteenth century, as contrasted with the expectant method of later years and the use of cardiac tonics and stimulants that have been too much given, especially the use of alcohol, which he considers damaging under all circumstances. If digitalis and carbonate of ammonium were used in combination with strychnia instead of alcohol the resulting fatality in a large proportion of cases would be avoided.

55. **Cryoscopy.**—The history of cryoscopy is given by Cattell, who finds that it has a valuable though limited field of useful-

ness. Its application is easy; it can be done at the bedside. Repeated cryoscopic urinary examinations in conjunction with those of the blood afford a valuable means of determining the presence or absence of renal and cardiac insufficiency, more particularly if ureteral catheterization can be performed. It should always be supplemented by the test for electric conductibility, the methylene blue test, the dilution test and other methods. It can be employed, according to Clowes, as a quantitative method for the determination of abnormal substances such as sugar and albumin, and as a qualitative test for beta-oxybutyric acid, formalin or water in milk, etc. The relation of specific gravity in health to cryoscopy is quite constant, but varies in diseases according to the quality of food and drugs taken, temperature, amount of sugar and salt in the urine, etc. There is a personal equation in making the test which should always be determined by the testing of distilled water under the conditions used in making the test. The cryoscopic index of the blood is quite constant, 0.56 to 0.58 C. Above this figure the blood is hyperosmotic, below this hyposmotic. In the former there is an insufficiency in the respiratory mechanism and secretion of the urine. The latter condition is noted in chlorosis and tuberculosis. While the index of the urine varies largely in health, cryoscopic examinations may be important corroborative tests in medicolegal cases, as in drowning. The salt freezing point of twenty-four-hour urine should not vary more than 1.23 to 1.69. If more than 1.69 we have oligochloruria; if less than 1.23, polychloruria. He suggests the direct relation of the blood index to viscidity of the blood.

56. **Nephritis of Gastrointestinal Origin.**—Favill calls attention to nephritis from absorption or intoxication from the gastrointestinal tract. As for treatment we should enforce rest, starvation, bowel disinfection and cardiac tonics. He believes that excess in eating is largely the cause of the tendency to this condition and reports a number of illustrative cases.

57. **The Early Diagnosis of Tuberculosis.**—Walsh points out the principal data which should guide us in the early diagnosis of phthisis; the higher temperature and pulse, loss of weight, etc. He warns against the use of obesity cures in persons that have had signs of tuberculosis earlier in life. He has seen rapidly developing and fatal tuberculosis follow too rapid reduction in weight under such circumstances. A cough of ten days to two weeks' duration should be considered with suspicion. There is no one symptom that is absolutely certain. A study of the individual case is required, but the points mentioned above give good reason for suspicion, and the environment and surroundings should be carefully studied in connection with them. He condemns the concealment from a patient that he has tuberculosis. He believes it is a bad practice on the part of the physician.

58. **Angioma and Its Treatment.**—Beck finds that one of the valuable methods in the treatment of angioma is subcutaneous ligation prior to incision. This reduces the size of the growth and avoids an extensive scar. Compression, as advised by old authors, is not advisable, nor does he consider the injection of styptics as reliable. The use of electricity in various forms is a valuable method, but the ultimate recourse is excision.

59. **Intestinal Anastomosis.**—Clark and Luther consider the Connell suture the most rapid and perfect method yet devised for end-to-end and lateral anastomosis, though for the closure of simple perforations or lacerations, or for exploratory incisions into the hollow viscera, Halsted's rectangular quilt suture is easy of execution and quite safe and is of decided preference. All mechanical devices for intestinal anastomosis should be discarded in favor of the Connell suture. Neither the suture within the bowel, as shown by the Wiggin-Connell method nor the Lembert suture and its modifications, should have the exclusive preference. Both are of great value in special fields and should be at the command of the surgeon to use as his best judgment dictates.

70. The Intercepting Sewer. William J. Carter.

66. **Radium.**—Metzenbaum gives the history of radium and its discovery and also the radio-active properties of thorium and other substances. He thinks that radium rays are destructive to living tissues, and the only hope for their therapeutic use is in their destroying the cancer cells before attacking the healthy tissues of the body. That healthy cells can be destroyed is sufficiently proven. Thorium being a very radioactive substance, may have some value in medicine or surgery, and he thinks it may come to be added to our list of drugs. In conclusion he reports a case of lupus treated by a radium tube of 7,000 activity and two tubes of 40 activity, with excellent results.

67. **Typhoid in Cleveland.**—The occurrence of typhoid in Cleveland during the last thirty years is briefly analyzed by Handerson. Accepting the idea that it is usually a water-borne disease, its history would point to a water supply always more or less defective and subject to attack of acute and severe infection with typhoid poisoning. The moderately high average mortality from typhoid fever, interrupted by short epidemics of greater or less severity, are noted.

68. **The Widal Reaction in Typhoid.**—Ladd has studied the Widal reaction in the present epidemic in Cleveland in some 454 cases at the Lakeside Hospital. The figures show that the Widal reaction was distinctly delayed in its appearance during the past six months; that it was less positive than was the case previously, and there were more anomalous cases than was formerly the rule.

74. Report of Two Cases of Meningeal Tumor Treated by Ligature of Their Vessels. Arthur Conklin Brush.
75. The Influence of Fever on the Pains of Locomotor Ataxia. Charles W. Burr.

71. **The Sensory Tract.**—Hoppe discusses the literature and reports cases bearing on theories of sensory localization. He concludes that: 1. Acute softening of the cortex of the area supplied by the middle cerebral artery produces in addition to complete hemiplegia a complete hemianesthesia. 2. Chronic degeneration and atrophy of the lower Rolandic tract due to thrombosis of a branch of the middle cerebral artery was not followed by a permanent loss of sensation of the opposite side of the face and arm. 3. Tumors destroying the cortical and subcortical region of the motor area very frequently have subjective disturbances of sensation such as pain, formication and numbness. Objective disturbances may occur, but are generally slight, and even in cases of severe motor disturbances leading to complete hemiplegia we do not ordinarily find sensory disturbances in proportion to the motor damage. He is inclined to favor the view of von Monakow that general body sensations have bilateral representation and that sensory impressions may reach the cortex by vicarious routes if their paths are destroyed. The chief cortical sensory areas, he thinks, at least for pain and temperature, are located in the anterior portions of the posterior lobe and the tactile and muscle sense in the Rolandic areas. Summing up the facts as regards the thalamo-cortical neuron, acute hemorrhagic destruction of the corona radiata between thalamus and cortex or acute cortical softening such as is due to thrombosis of the middle cerebral artery lead to hemianesthesia. Hence he thinks the physiologic character of the thalamo-cortical neurone as a sensory tract may be accepted. On the other hand, chronic lesions of this region may and often do exist without causing any pronounced disturbances of sensation, and this leaves us but one explanation: Von Monahow's theory of bilateral representation.

79. A Rapid Procedure for the Estimation of the Peptic Value of Stomach Fluid by Means of the Mett Method. David Murray Cowie.

77. **Resection of the Nasal Septum.**—Anderson advocates Krieg's operation recently developed by Freer (see THE JOURNAL of March 8, 1902). He describes the method and claims that it has the advantage of being more easily adapted to irregular septa, the after-treatment is shorter and simpler and there is no necessity of confining the patient to bed. He reports 12 cases in which he performed this operation, 10 men and boys, and 2 women. All were improved and most were entirely relieved of all troublesome symptoms. Two cases were not quite successful, one apparently on account of the narrow space in which he had to work and the other due to a severe *trauma which could not have been relieved by any single operation.* In his early cases he had 3 perforations, but since becoming more familiar with the method and having the proper instruments, he has not had a single case of this sort. On the whole it appeals to Anderson as the most satisfactory operation for the correction of deflections that we have.

81. **Mastoid Operations.**—The experience of Barnhill is here reported as favorable to mastoid operations. His fatalities were only 3 out of 100, and none of these was due to the operation when performed in cases where no intra-cranial complication existed. The deformity left even in extensive operations he considers slight, and the results as regards the cure of the mastoiditis and the discharging ear have been generally good, especially in the acute cases where it was ideal. In chronic cases they were not quite so striking, and he thinks that in such the so-called Schwartze-Stacke operation should be done only after other means of cure have been fairly tried; for he has had many recoveries after the removal of dead ossicles and clearing out of the existing granulations or other diseased tissue in cases that, according to the advice of others, would have been treated by the radical method. Three cases of cerebral complications are reported.

1. **Rheumatism.**—Poynton reports a fatal case with postmortem and bacteriologic findings. The diplococcus was cultivated in tubes inoculated from valves, spleen and kidneys. The cultures from the lung were not pure, but the diplococcus was present among other micro-organisms, while those of the pericardial fluid and blood gave negative results. This last he says emphasizes a point to which with Dr. Paine he has already called attention. It is that these micro-organisms, when they occur in the body, grow best in local lesions, and though they are often present in the blood, they do not thrive in it. They are not easily found in recent exudates, for they lie in the synovial tissue and not in the synovial fluid of the joint; in the pericardium itself, and not in the pericardial exudations. Therefore, in slight attacks of rheumatic fever, neither examination of the blood nor synovial exudation will often result in success in finding the germ. If the infective agent was always present it would indicate a much more terrible disease than actually exists. Inoculation experiments on monkeys and rabbits were successful. He discourses on the practical application of the infective theory of rheumatism, pointing out the stimulus that it gives to a study of the action of bacterial poisoning in the pathogeny of gout, and also the identity in structure of the cardinal lesions of rheumatic fever, which now rests on good evidence. Endocarditis, pericarditis, arthritis, pleurisy and nodule formation are lesions of the same type, allowance being made for their anatomic situation. He thinks the view also helps us as regards treatment. Without saying anything in regard to serumtherapy, which is not past the critical point of its development, we can now see the phase in rheumatic fever when infection has the upper hand and where it is being vanquished and the healing processes have begun. Thus we can bring into action the assistance of hydropathic measures, radiant heat, electricity and other methods to aid in the recovery. He believes it is time to study up rheumatic fever, the influence of climate, overcrowding, contagion, etc.

2. **Abdominal Pain in Acute Rheumatism.**—Pearson calls attention to a symptom which occurs in certain cases of children of a sort of abdominal pain in the upper half of the abdomen, starting from a point a little below the costal margin, close to the middle clavicular line on either side and running from there either toward the umbilicus or straight across. The etiology is obscure. The treatment is that of the general disorder. He reports several typical cases.

3. **Sterilized Milk.**—The dangers of trusting too much to sterilized milk are pointed out by Robertson and Mair, who divide bacteria in milk into three classes: 1. The non-spore-bearing, including cocci, lactic acid, coli and proteus groups, easily killed by exposure to 100 C., or heating for a short time at a temperature of a little over 90 C. Pasteurizing for half an hour also kills these bacteria. 2. The butyric acid bacilli, the anaërobic, spore-bearing forms, killed by exposure for one to one and one-half hours at a temperature of 100 C. To this group belongs Klein's *Bacillus enteritidis sporogenes*. 3. The bacillus subtilis group. There are aërobic, spore-bearing bacilli, decomposing milk with a faintly acid or unchanged condition, causing coagulation of the casein and subsequent liquefaction of the coagulum. Flügge attributes the summer diarrhea of children largely to these "peptonizing bacilli" and has isolated twelve distinct species from samples of market milk. He concludes that most of the so-called sterilized milk on the market is unreliable and likely to cause harm. The authors think if Flügge's view is right, the reproach against partially sterilized milk is serious, but most practicing physicians will be of the opinion that Group 1 is the real culprit in most cases, as boiling the milk seems to relieve the intestinal disorders of children. They have examined the specimens in milk supplied to infants from the infants' milk depot of the Leith corporation and conclude that the designation "sterilized milk" is wrong and misleading, and would suggest substitution of the name "milk prepared for infants." Every customer should be carefully instructed as to the necessity of keeping the milk as cool as possible, especially in summer. Faith in steam sterilization should not be too implicit. In hot weather each daily supply should be sold as it is prepared. As an additional precaution, all bottles after being taken from the sterilizer should be placed in warm water gradually cooled as the placing of warm bottles in cold water would lead to their breaking. They insist on the importance of cleanliness on the part of the cow keeper as an important adjunct to the general movement for wholesome milk.

5. **Intestinal Tuberculosis.**—From Hunter's researches in Hong Kong, where, out of 5,142 consecutive necropsies, only 13 cases of intestinal tuberculosis were found, and 8 of these considered as a secondary infection, being derived from tubercle foci in other parts of the body, leaving only 5 to be regarded as instances of primary intestinal tuberculosis. His conclusions are that primary tuberculosis of the intestine is rare under 5 years of age, and that tuberculosis of the mesenteric glands is also rare. These results, derived from a native population where tuberculosis is rife in all its forms and conditions exceptionally favorable for its dissemination, point to the alimentary canal as a rare avenue through which infection is conveyed in childhood.

6. **Intubation.**—Biernacki and Muir from their experience would use intubation as a treatment in laryngeal diphtheria as against tracheotomy in the absence of clinical contraindications. Among these they mention severe involvement of the fauces and nasal passages, though even in severe cases intubation is not often contraindicated. With palpable edema of the upper part of the larynx, ulceration is a danger in some cases. The presence of membrane low down in the trachea as a contraindication is in doubt. In two cases intubation gave relief, although subsequently casts showing the bifurcation of the trachea were coughed up. The last condition noted is a moribund condition referable to obstruction, and there is a possibility that the temporarily increased asphyxiation involved in intubation is inadmissible in such cases. An extensive bronchopneumonia as a contraindication is considered, and they doubt whether intubation has really an effect on it. If there is much tenacious sputum, intubation may be rendered ineffectual by constant blocking of the tube, but such a contingency can not well be foreseen. If there should be a severe blocking of the tube and intubation only partially relieve it, tracheotomy would have to be performed; otherwise time should be allowed for the child to settle down. They do not believe in retention of the tube under ordinary conditions past the fourth day. It should then be taken out and kept out, if possible.

7. **Puerperal Convulsions.**—Helme advocates theoretically the use of spinal subarachnoid puncture as a relief for pressure symptoms so obvious in puerperal convulsions, he considering that increased intracranial pressure is largely the cause of the condition.

8. **Blood Disorders.**—Hutchison's second lecture discusses the splenic anemia of infancy and its relation with that of adults. He points out the curability of the former, and discusses its etiology, pathology and causation. He thinks that it is true that both forms of splenic anemia may occur in children, and reports a case which seems to indicate this. Still, he considers the two diseases ordinarily quite distinct. The leukemia of childhood in its different forms is discussed, as also the mixed forms. He thinks that the tendency is in favor of attaching more importance to the type of cell found in the blood and less to its special seat of origin, and ventures to prophesy that in future the leukemias will be classed on the former basis, instead of as hitherto on the latter; that we will speak of myelocytic, lymphocytic and mixed-cell leukemias, rather than of myelogenous or lymphatic. Only in such a way will the present confusion in classification be reduced to order.

9. **Infective Gangrenous Necroses of the Alimentary Tract.**—Corner, from an examination of the records of cases of obstruction of the mesenteric vessels, deduces the following tables:

CLINICAL TABLE.

1. It is most common in men past middle life. 2. It is most common secondary to valvular disease of the heart, especially mitral disease. 3. The onset is generally sudden, with symptoms of peritonism. 4. In one class the picture is one of intestinal obstruction or peritonitis, due to appendicitis or the perforation of a gastric ulcer. 5. There is also another class in which the blood is passed per rectum, and which signifies infarction of the bowel. 6. Subacute and chronic cases are seen, as well as the most acute. 7. In some cases it is most probably spontaneously recoverable from, especially if only a small area of the bowel is rendered bloodless.

PATHOLOGIC TABLE.

1. For a constant situation of the embolus in the superior mesenteric artery, as in the main trunk, all varieties of clinical cases have been reported, from the most acute and fulminating to cases like Professor Chiene's that recovered apparently without obvious symptoms. 2. With a precisely similar lesion some subjects die in thirty hours, and some not for from twelve to twenty days. 3. Gangrene of the gut has been noticed to occur within thirty hours, and sometimes not after twenty-two days. 4. A collateral circulation can be formed in slowly developing cases of visceral vascular obstruction—e. g., Professor Chiene's case. And even in more acute instances an attempt at a collateral circulation is made. 5. The superior mesenteric artery is almost invariably picked out for the site of the embolus in fatal cases, possibly because it will always cause symptoms and almost always death, which need not occur with involvement of the inferior mesenteric and its branches or those of the celiac axis. 6. The explanation of the individual variations, clinical and pathologic, seems to depend on the pathogenicity of the bacteria present in the gut as to the severity, rapidity or other characters of the cases. On the bacteriology of this affection there is no work done.

11. **Hydrophobia.**—Thorpe finds that the Chinese have a remedy for hydrophobia, consisting in the powdered nut of a Strychnos, probably Strychnos nux vomica. It is said to cause the patient to fall into a sleep in which he sweats profusely and awakes cured. Assuming the ordinary proportion of strychnia in the nut, it would be from 1/33 to 1/13 of a grain in each powder. He finds no reference to this as a remedy for hydrophobia, and suggests that the Chinese have applied the principle of *similia similibus* from some certain resemblance of symptoms.

13. **Diabetes.**—Allan advocates the use of the organic treatment by the transplantation of the pancreas into the patient under the following conditions: When, after a full and honest explanation, the patient requests it, and it is ascertained that the patient is not suffering from acetonuria at the time, and that the sheep shall be killed close to the place of operation and its pancreas directly conveyed to the body of the patient.

15. **Neuroretinitis in Chlorosis.**—Evans notes the occurrence of fundus changes in chlorosis and their neglect nevertheless by ophthalmologists. He insists on the importance of early diagnosis of neuroretinitis in these cases to prevent permanent damage to the eye. No satisfactory theory as to the cause of neuritis and hemorrhages has been propounded as yet. The treatment is the ordinary treatment for chlorosis by iron, with or without arsenic, and due attention to the intestinal tract. Five cases are reported by him.

19. **Neoplasms.**—Vallack opposes the parasitic theory of neoplasms, and suggests that the tumor formation is the perverted relic of a lost ancestral function, namely, a sexual reproduction, supporting his view by the occurrence of neoplasms most frequently in the young, or in the aged, when the sexual powers are either undeveloped or are on the decline, their heredity, the effects of irritation as producing proliferation with abnormal rapidity on cell reproduction, and the fact that certain localities seem to be particularly prone to the formation of these growths. He does not refer to the recent work by English authors showing the resemblance in the mitoses of cancer cells to those of the reproductive cells, in support of his argument.

23. **Leucocyte Curve in Surgical Affections.**—Julliard comments on the fact that no physician relies on occasional, casual thermometer readings in his estimation of the temperature in disease. He insists on the general curve of the temperature chart and bases his diagnosis on the characteristics of the curve as a whole. No one, however, applies this rule to the blood count. An occasional numbering of the leucocytes is supposed to be all that is necessary for the diagnosis of surgical affections, whereas in reality it is the general curve of the leucocytosis which is decisive. Those who doubt its clinical value are those who have been content with an occasional leucocyte count. It should be observed in connection with the temperature and the pain, these three forming the "symptomatic trilogy" whose elements should never be separated. The leucocytosis frequently precedes the fever, which gives it unusual diagnostic importance. In suppurative appendicitis the number of leucocytes may increase to 25,000. This figure is the lower limit of suppuration. The figure must remain at this point or above for several days at least to affirm the positive presence of pus. The number of leucocytes at the onset is no criterion. The curve alone, as the affection progresses, is of importance for the diagnosis. The leucocytosis increases if the abscess has a tendency to spread, and decreases as its virulence becomes attenuated or it becomes encapsulated. The leucocytosis abruptly subsides in case of evacuation of the abscess, whether by surgical intervention or by perforation into the intestine or bladder. If the leucocytosis persists after surgical evacuation of the abscess there must be some second focus or metastasis or some complication of a different kind, such as pneumonia. When the abscess perforates into the abdominal cavity the leucocytosis subsides at first, but rises again as peritonitis develops. The absolute number of the leucocytes is of more diagnostic import than the proportion of the different varieties. The article is continued.

24. **Surgical Treatment of Rectal Prolapse.**—The three-fold indications in treatment of prolapse of the rectum are the reconstruction of the perineum and the anal canal, reduction of

the size of the ampulla and suppression of Douglas' pouch when it is abnormally large and especially when there is hernia into it. The technic which Duval and Lenormant use and recommend includes intervention both behind and in front of the rectum. The rectum is first suspended from the sacrosciatic ligaments and then the anterior wall of the rectum is taken up in vertical and horizontal folds, the suturing threads emerging through the levatores ani. Two cases thus treated are described and six illustrations show the various steps of the operation. The results, both immediate and remote, have been extremely satisfactory.

25. Enhanced Resisting Power of Peritoneum in Appendicitis.—The abscess formation is preceded by diffusion of toxins from the at first diffusively inflamed appendix. These diffused toxins induce the production of antitoxins, which are thus on hand, ready to cope with bacterial invasion after perforation of the appendix, and they allow the peritoneum to be opened up with comparative impunity at this stage. This explains the rapid recovery from the peritonitis as soon as the appendix is removed, if the operation is done in time. The diffuse serous effusion, which is the first reaction to the diffusion of the toxins, is an indication of their presence. Its amount, likewise, is an indication of their virulence. (See abstract of Moszkowicz' first communication on this subject of the diagnostic importance of the serous effusion in appendicitis, page 686.)

27. Intraperitoneal Rupture of the Bladder.—An important sign of this occurrence is the finding of the bladder completely empty, while a large amount of urine pours through the catheter when the latter has found its way through a large rupture. When the rupture is extraperitoneal there is usually 50 to 100 c.c. or more of urine left in the bladder. Seldowitsch describes a case and reviews those that have been published in Russia and elsewhere, a total of 39 cases of recovery after intraperitoneal rupture of the bladder. The proportion of recoveries has been small to date, but the prognosis is growing better. An incomplete should be sutured like a complete rupture. Fatal peritonitis is frequently due to infection during catheterization. In the personal case reported he left a catheter continuously in the bladder for two weeks, changing it every day and carefully cleansing the outer orifice of the urethra each time before inserting it. The patient was a woman of 27 and an interval of three days elapsed before the laparotomy. The urine had been drawn three times with the catheter in the interim. Very little urine could be found on two occasions, but 1,600 c.c. came the last time. The rupture was 6 to 7 cm. long and was sutured in two tiers. Recovery was rapid and complete.

28. Formaldehyd Dry Sterilization.—Tests of the Percy Simundt sterilizer at von Bergmann's clinic showed that it is an excellent means of keeping sharp instruments and catheters sterile, but it is not so practicable for sterilization of dressings, etc.

29. Infection of Wounds from Speaking During Operations.—Mendes de Leon arranged a box with agar plates on the bottom and spoke over it the words usually said during the course of a laparotomy, a total of 60 to 100 or 200 words—all the conditions approximating those of a major operation. He estimates that there were at least 4,375 micro-organisms in every droplet of saliva. Four kinds of bacteria developed on the plates, streptococci, diplococci, staphylococci and sarcinæ. Some of the streptococci proved very virulent, more so than streptococci in the saliva in the mouth. He thinks that more attention should be paid to the danger of infection from this source, and advocates the use of a mouth mask he has invented to obviate it. He gives details of experimental inoculation of 61 animals with the agar from plates over which the same words were spoken as had been used in some preceding operations (Dutch and German). His mouth mask is made of fine wire netting in the shape of a roomy cap or box, fitting over the mouth and part of the cheeks. There is a layer of cotton between the top of the box and its perforated cover. The mask is very light and is held in position by a spring around the ears like spectacles.

44. Sounding and Radiography of the Large Intestine.—Schüle has been testing various sounds, including Kuhn's flexible spiral sounds and also the Kassel soft tubes with flexible *metal guide, terminating* in a button 5.5 to 8 cm. in circumference, thus obviating all danger of perforating the intestinal wall. He gives radiograms of the findings. His conclusion is that no convincing proof has been obtained to date that a sound has been successfully passed into the descending colon, to say nothing of the transverse portion. The innumerable folds, windings and swellings of the intestine render it impossible to determine whether an obstacle to the progress of the sound is of a natural or pathologic nature. On the other hand, the direct visual inspection of the rectum and sigmoid flexure by the J. Schreiber and H. Strauss *technic is perfectly* reliable. Schüle found that "high injections" were practicable, the best vehicle being oil. An injection in the knee-elbow position of 300 to 400 c.c. of oil with 125 gm. bismuth subnitrate, followed by radiography, showed that the oil had penetrated to the ileo-cecal valve. He gives some instructive radiograms thus obtained. In 2 of the patients there was pronounced enteroptosis, the transverse colon in one hanging suspended like a garland from the two points of attachment at each end, the center reaching far below the upper plane of the pelvis. He gives a radiogram of a normal child for comparison. On account of the small amount of the oil injected and the fact that the subject was in the knee-elbow position at the time, the injection could not have been responsible for the sinking of the intestine. The radiograms show perfectly the topography of the colon for its entire extent. They also prove that the ileo-

58. Foreign Bodies in Esophagus.—The 3 cases described were treated by esophagotomy and the findings demonstrated the great dangers to which the subjects are exposed in such cases without prompt operative removal of the foreign body.

59. Acute Infectious Osteomyelitis.—Trendel completes the statistics previously published from von Bruns' clinic, classifying the material according to sex, age, occupation, etiology, localization, etc. The total is 1,110 affections of long bones and 169 of others. He also gives the direct and remote results.

64. Ileus.—Braun denounces the use of opiates and lavage of the stomach, as the relief afforded masks the symptoms. The results of surgical intervention depend on accurate diagnosis. All cases of ileus, due to mechanical obstruction or to organic stenosis, should be operated on at once, as there is little chance of spontaneous retrogression. Surgical intervention alone is not able to cure the patient. It must be supplemented by medical measures directed against the dangerous disturbances in the nervous system, circulation and intestinal function, which are liable to be all seriously compromised in cases of ileus. These medical measures need further enlarging and perfecting. Our present equipment is rather meager, he thinks.

69 *Ueber percutane Campbor-Anwendung, speciell bei Lungen-Tuberkulose. W. Koch.
70 Radium Holder. M. Einhorn (New York).—Radium-Behälter für den Magen, Oesophagus und Rectum.

65. Facial Anomalies which Affect Growth of Extremities.—Babes presents arguments to prove that there is a center which presides over the development of the limbs. Any displacement or deformity in this center is liable to entail abnormal growth of the limbs. He means especially the tendency to a missing toe or finger or an excessive number, or the blending of two fingers or toes into one, or the excessive development of one. These three classes may be combined in various groups, but they are always symmetrical. He calls this tendency to symmetrical deformities "acrometagenesis" and places the center for it in the anterior base of the skull, in the upper part of the face. In a large number of monsters he has found these facial anomalies very pronounced, as he describes, when the acrometagenesis was particularly striking.

66. Interpretation of Findings of Blood Traces in Feces.—Joachim's research was undertaken at Königsberg and it has confirmed the announcements of Boas and others in regard to the differential value of "occult" blood findings in the feces. In only 1 out of 18 cases of cancer of the stomach were the findings negative. In 83 per cent. of 28 cases of ulcer of the stomach the findings were likewise positive at some times, but not at others, thus differentiating the ulcers from the more constant findings in case of cancer. Ingestion of raw or rare meat is liable to prove a source of error, and also the fact that blood is apt to be found in the feces for several days after a single copious hemorrhage. In 2 out of 6 cases of typhoid the finding of blood in the stools proved to be a forerunner of a severe hemorrhage a day or so later. Traces of blood were also found in the feces in case of uncompensated valvular heart defects, but they vanished so soon as the congestion subsided. Blood was found in a case of catarrhal icterus, but never in cholelithiasis except once the day following an examination of the stomach. The guaiac test was also positive in case of secondary cancer of the liver and in one instance of cancer in the cystic duct. The findings were negative in a case of cancer of the pancreas, but were positive in a hemorrhagic pancreatitis. As many as 450 tests were made to determine the amount of blood ingested which would give positive response to the parallel guaiac and aloin tests. Even as little as 3 gm. of blood gave a faint response. Sometimes one of the tests would be positive while the other was dubious. Spectroscopic tests for hematoporphyrin were positive only when the other tests were markedly positive.

67. The Heat Rays in Phototherapy.—Scholtz ascribes much of the action of Finsen treatment to the penetration of the tissues by some of the heat rays. They affect the more highly colored parts below the surface more strongly than the surface itself, and the effect of stains is also to enhance the action of the heat rays. This explains the benefit of preliminary "sensibilization" according to Dreyer. It also explains why the brownish, subcutaneous patches of lupus feel the effect of the phototherapy more than the sound skin above them. The heat rays, he finds, have a peculiarly strong—an elective—action on them, as also on any deep-seated structures previously colored with some stain.

68. Pericarditis and Puncture.—In 37 out of 56 cases of pericarditis observed by Doebert there had been preceding articular rheumatism. Only 8 of this class of cases succumbed, the rest recovered. The mortality was a little higher in the other cases of different etiology. He describes a few instructive cases to show that puncture made in the right side was able to produce the desired effect after failure of puncture in the left side. In one case very little could be evacuated as long as the subject reclined, but as soon as he sat up and leaned forward the fluid flowed freely. The heart must have been floating on the surface of the accumulated fluid, its suspension possibly aided by adhesions.

69. Camphor as Valuable Adjuvant in Tuberculosis.—For five years Koch has been making systematic use of camphor in pulmonary tuberculosis. At first he gave it in subcutaneous injections of 1 gm. of camphorated oil daily for four days with ten-day intervals. His results were extremely satisfactory, but the injection method has its drawbacks, so he gives the camphor now in inunctions. He makes a salve with about .4 gm. camphor in the amount rubbed in at one time. He uses percutilan as a vehicle, a new substance which he says "actually slips through the skin." A little balsam of Peru is added and eucalyptus and rosemary oil. These inunctions are made by the patient on five successive days and then a ten-day pause. The amount of sputum increases remarkably by the second day and then expectoration almost ceases, while the other symptoms are correspondingly improved. Equally favorable results were observed in emphysema and bronchitis.

71. Constipation Due to Too Perfect Assimilation.—Lohrisch has found by his researches on metabolism that certain cases of habitual constipation are due to excessive utilization of the nourishment ingested, thus leaving too little refuse to be expelled. The flora normally in the intestines do not find the scanty fecal substances an appropriate culture medium, and there is not sufficient fermentation and putrefaction to stimulate peristalsis.

72. **Agglutination of Typhoid Bacilli in Proteus and Staphylococcus Infections.**—In 2 cases of a proteus and staphylococcus ear affection, the blood serum was found to have notable agglutinating power for the typhoid bacillus. Experiments with rabbits and guinea-pigs showed that inoculation with proteus as also with staphylococcus cultures had a marked influence on the increase of the agglutinating power for the typhoid bacilli. Cultures of streptococci, Asiatic cholera and other germs showed none of this effect.

76. **The Phonendoscope.**—Sehrwald insists that the phonendoscope can be made to give variable findings at will, and that it is by no means as reliable as the ordinary stethoscope.

79. **Metabolism in Hyperthermia.**—Linser and Schmid had occasion to observe a brother and sister with universal ichthyosis hystrix affecting the entire body, except the face. The sweat glands were incapable of functioning anywhere except on the face. In a hot-air apparatus their temperature rose twice as fast as that of control subjects owing undoubtedly to the lack of the radiation of heat in the sweat secretion. There was no increase in the elimination of nitrogen, even during long-continued high temperature, if it did not go above 102 F., but this followed whenever 104 was reached. Other particulars of the metabolism in hyperthermia were exhaustively studied on these subjects. The application of the heat had an unmistakably beneficial action, evidently improving the functioning of the skin, as also in 3 cases of acne. The experiments showed that increased elimination of nitrogen in the urine consequent on very high temperatures, is paralleled by an increase in the purin nitrogen, ammonia, amido-acid nitrogen and phosphates. There was no evidence, however, of sugar, acetone, acetic acid or beta oxybutyric acid albumin or of formed elements. The respiratory quotient grew smaller.

80. **Influencing of Coagulation in Living Organism.**—The details of 83 tests on animals and 10 on human subjects are tabulated to show the influence of gelatin and other substances on the coagulation of the blood. The practical results are that calcium lactate has a decided influence in this respect. This influence is most marked in subjects with pathologically low coagulating property. He gave 1 to 2.5 gm. a day, with 3 gm. in one case and 30 gm. in another. The increase in the coagulating property under its influence subsided after two or three hours. The only instance in which it failed to exert this action was in a case of pernicious anemia.

83. **Chronic Nutritional Disturbances in Infants.**—Steinitz summarizes his numerous researches in the assertion that a milk rich in fat causes a loss to the infantile body in fixed alkali. The fat causes more alkali to be used up in the intestines and evacuated in the feces. This entails an increased output of ammonia to compensate this loss of alkalies.

87. **Cerebrospinal Meningitis.**—Soerensen reviews the pathology and symptomatology of 60 cases of cerebrospinal meningitis. In the 19 cases that came to autopsy tuberculous foci were found in 4.

88. **Bacteriuria in Children.**—Mellin has found only 11 cases on record in the literature, and adds 10 observed at Helsingfors. The colon bacillus was responsible in 8 cases, and the staphylococcus albus in 2, a lad of 10, and an infant. The symptoms were unimportant, and treatment with salicylates and local rinsing out the bladder with a weak disinfectant speedily cured the condition.

96. **Polymyositis in a Boy of 7.**—After recovery from whooping cough the child had a fever for four days with dyspepsia and a fleeting exanthem, followed by symptoms of pronounced polymyositis. After persisting three weeks all the symptoms vanished and recovery was complete in eight weeks. Schüller compares with this the similar cases on record, with others of progressive ossifying myositis, etc. There are only 5 other cases of primary acute polymyositis in children—like his case—on record. One was of a fibrous type, one a dermatomyositis; one was consecutive to an infectious sore throat and one to some other infection. One child recovered completely in a few weeks, and one after a few months, but the others were left with paresis and atrophy of some of the muscles.

97. **Agglutination in Scarlet Fever.**—It is still an open question whether the streptococcus is the causal agent of scarlet fever or merely a secondary parasite. The experiences related show that scarlet fever streptococci are agglutinated by serum from scarlet fever patients, but that the serum loses this property as convalescence terminates. Streptococci from other sources are not influenced by scarlet fever serum, and serum from other sources does not agglutinate the scarlet fever streptococci. Passage through animals attenuates, but does not entirely abolish the agglutinating property. The agglutination observed indicates, however, that there is some direct biologic connection between the streptococci and the scarlet fever subject. Notwithstanding this, Hasenknopf and Salge do not think we are justified in assuming that the scarlet fever streptococcus is necessarily the specific causative agent. They are also very dubious as to whether an antistreptococcus serum derived from the horse will find in the human body the needed complements.

102. **Diphtheria Bacilli in Infantile Coryza.**—Ballin found diphtheria or pseudo-diphtheria bacilli 11 times in 63 children suffering from ordinary coryza. In 9 instances the bacilli were virulent. He accepts them as accidental parasites, never the cause of the coryza. He does not regard the presence of the bacilli as menacing, but the children are closely supervised and antitoxin is injected whenever symptoms develop that even remotely suggest diphtheria. Actual diphtheria has never developed in a single instance. The communication proceeds from the Berlin Children's Asylum (Kinderasyl).

105. **Head's Zones in Children.**—Bartenstein's experience at Breslau confirms Head's assertions in regard to the increased sensitiveness of certain zones of the skin in case of affections of the internal organs. He found them frequently in children over 3 years of age. These findings will explain a number of hitherto mysterious phenomena which have been ascribed to hysteria or neurasthenia. He also found that the trembling of the muscles of the eyelids when the eyes are shut is of frequent occurrence in the offspring of neurasthenic parents. He found the Head zones in 46 cases of various internal affections, and believes that it may prove possible to influence the internal affection by revulsion applied to these zones.

119 Permanent Results of Operations for Displacements of Uterus. J. Sonnenfeld (Berlin).—Ueber die Dauererfolge der Operationen bei Falschlagen des Uterus.

112. **Primary Carcinoma of Clitoris.**—Jacoby warns that long-continued eczema or pruritus should suggest malignant disease in the clitoris. Neoplasms here seem to be always malignant. He reports 2 cases. One was inoperable. The other patient was cured by ablation of the growth. He gives the outlines of 65 cases from the literature. Eleven patients were permanently cured by extirpation of the growth.

113. **Remote Results of Operations for Prolapse and Retroflexion.**—Analysis of the results after 217 various operations for these conditions compels Baatz to the following conclusions: Prolapse of the vagina without retroflexion should be treated by plastic intervention. When associated with movable retroversion in the childbearing age, and all primary prolapses of the uterus, prolapse with immovable retroflexion, and very large and total prolapses, ventrofixation with a plastic operation on the vagina offers the greatest chances for successful intervention. Vaginofixation is preferable for prolapse of the vagina and movable retroversion in the climacterium, especially if the intervention is completed by a plastic operation. In cases of isolated retroflexion, either movable or not, ventrofixation affords the best remote results. Supravaginal amputation of the portio is indicated for much hypertrophy of the portio or elongation of the cervix.

114. **Vaginal Removal of Uterine Cancer.**—Schauta remarks that no one yet has systematically studied the behavior of the higher glands in case of carcinoma of the uterus. Only a few persons have investigated even the inguinal and preinguinal glands. He has been studying various groups of glands from this point of view. The largest gland found was cancerous, and measured 12 by 18 mm., but others, nearly as large, were entirely free from cancer, one measuring 12 by 15 mm. The smallest cancerous gland was 1 by 1 mm. He found cancerous degeneration in 271 out of 1,182 glands examined, and of this number only 43 were sacral glands; 91 were iliac glands; 44 were the lumbar glands on both sides of the aorta; 19 were celiac glands along the aorta upward to the root of the diaphragm; 32 were superficial, and 42 were deep inguinal glands. The glands were entirely free from cancer in only 25 of the 60 cases examined. The most significant result of this research is that in such a large number of cases the accessible glands—those usually inspected and removed during an operation—were sound, while the remote, inaccessible glands—those included in the four last-mentioned groups above showed cancerous degeneration. In 35 per cent. of the total number of cases it would have been useless to remove the glands below, as the higher located glands were already involved. In only 13.3 per cent. were the high glands sound. Large, hard glands frequently show no trace of involvement, but cancer elements may be found not only in the connective tissue and lymph spaces, but also in veins between sound glands. The facts related demonstrate that the complete removal of the cancer with all its involved glands, if the glands are involved at all, is possible only in the rarest cases. A cancerous focus in a gland is liable to remain in the gland like an inclosed foreign body. After the removal of the primary focus the glandular focus generally subsides into a dormant condition, from which it may never arouse, or it may commence to proliferate during the menopause. In the second part of his article, Schauta reviews his clinical material with vaginal extirpation. The results confirm his advocacy of the vaginal route, which he has followed in 91 cases since 1901. Only 45.4 per cent. of the 239 cases that came to the clinic proved to be operable. The mortality was 12 per cent. He prefers the Schuchardt paravaginal incision, except when the vagina is exceptionally wide and elastic.

115. **Interference with Childbirth After Ventrofixation.**—Lynch has found 20 cases on record similar to the one he describes, in which cesarean section was necessary after ventrofixation to deliver the child. The fixation in some cases had not been intentional, but was due to adhesions developing after mere suspension.

117. **Struma of the Ovary.**—The diagnosis of this condition is aided by finding a large amount of effusion with a comparatively small tumor. When its strumous nature is seen as the ovary is exposed, the surgeon can leave the other ovary untouched during the childbearing age, as the affection has always been found unilateral to date and relatively benign. In all the cases known the left ovary was the seat of the lesion, and the patients had all passed the reproductive period.

120. **Blood and Urine in Eclampsia.**—Zangemeister first established by comprehensive research on normal pregnancies and childbirths the standards for comparison with the eclamptic

cases. He determined the alkalinity of the blood, number of formed elements, chlorids, concentration of serum, freezing-point, etc., and for the urine, the acidity, proportion of the constituents, etc., establishing the "chlorid quotient," that is, the relations between the chlorids and the total salt molecules. He found the kidneys always anemic in eclamptic subjects, but nothing to indicate an uremic etiology for the eclampsia. The most striking change in the blood in eclampsia is the marked hyperglobulia, evidently due to loss of plasma. The chlorid quotient is usually constant, but in eclampsia it varies considerably. It averages much lower than in normal parturients, even down to 2 per cent.—and is very much less than during pregnancy, the average for which is 40 per cent. This phenomenon is probably due to some sudden interference with the circulation through the kidneys, manifestly the result of some contraction of the vessels in the kidneys. These contractions are part of the labor contractions and, in fact, the onset of the convulsions in eclampsia corresponds with the periods of rhythmic contractions of the uterus. Labor is unusually vigorous in eclampsia. Women with exceptionally energetic labor contractions are particularly prone to eclampsia. It is liable to come on with the first labor pains, especially in primiparæ and in case of artificial delivery. The labor contractions have long been known to have an unmistakable influence on delivery albuminuria. The labor pain is accompanied by contraction of the arterial blood vessels. This entails injury to certain organs, as their nourishment and function are impeded, and fatty degeneration, infiltration or anemic necrosis is liable to result. The sudden anemia in the brain causes convulsions, the anemia in the kidneys checks the elimination of water and of salts through them. This conception of eclampsia does not exclude the action of toxins, but shows that it is possible without them.

125. **Struma Ovarii.**—Walthard's 3 cases were distinguished by the large size of the tumors. One measured 11.5 by 7 cm.; one 6 by 8.5, and the other 13.5 by 7 cm. Each was examined in frozen sections. One patient is in perfect health years after the removal of the cystic tumor. Two of the tumors were evidently teratomata, with degeneration of the inclosed thyroid tissue.

130. **Conservative Myoma Operations.**—Winter knows of 10 abortions in 64 cases of pregnancy after simple ablation of subserous myomata, and 11 abortions in 58 cases of pregnancy after enucleation of subserous interstitial myomata—all operated on during the pregnancy. The children survive unharmed in all but one-sixth to one-fifth of such operations during pregnancy. The latter does not seem to render the operation any more serious for the woman. The statistics from the German clinics show that the prognosis of supravaginal amputation is worse than that of conservative enucleation. He concludes from his own and the experience of others that myomata of the uterus should be operated on radically, as a rule. Conservative intervention is indicated only when the patient is very anxious for offspring and wishes to retain the function of menstruation. Only one-fourth of the women were satisfied with the results of conservative operations in his experience.

131. **Freezing-Point of Blood in Pregnancy and Parturition.**—Füth announces that he found the freezing-point of the blood .035 to .04 of a degree C. higher in pregnant women and in parturients than in the non-pregnant and non-parturient.

132. **Oxygen in Fetal Blood.**—The same writer describes comprehensive research along analogous lines on rabbits, further determining the influence of carbonic acid and of oxygen on the freezing point of the blood of gravid and non-gravid rabbits. He also presents arguments to sustain the view that human fetal blood contains oxygen. Among them he mentions the long interval that elapses before children extracted by cesarean section commence to breathe. The apnea may last several minutes.

138. **Loss of Blood at Childbirth and Its Consequences.**—Ahlfeld has the blood lost by the parturient collected by a funnel-shaped contrivance in the bed, opening into a graduated receptacle below. When more than 400 c.c. has escaped a physician is summoned. The average amount is 400 to 500 gm., but even larger amounts may be lost in normal births. The amount is usually proportional to the size of the child and the connected size of the placenta expanse and its weight. Pluriparæ lose more than primiparæ. The largest amount noted was 3,000 gm., and it caused comparatively little disturbance in the general health. A loss of 1,500 gm. is well tolerated by certain women, while in other cases it proved fatal. The morbidity of the puerperium is liable to be increased after considerable losses of blood. He was not able to detect any appreciable influence on the nursing capacity. He preaches constantly that the first half hour after the birth belongs to the woman, not to the child. His funnel bed has an opening in the mattress 22 cm. in diameter, into which fits a flat-edged, nickel-plated funnel, the tapering end projecting a few inches below the bed. A graduated cylindrical glass receptacle below catches the blood, after the thin pad and rubber sheet under the woman have been removed after delivery, and substituted by a sheet with a hole in the center. The blood that drips from the pad is measured, too, and also the blood lost with placenta.

THE PHARMACEUTICAL EXHIBIT.

The Exposition of Remedial Agents, Surgical Instruments, and Other Physicians' Supplies at Atlantic City.

One of the interesting features of medical society meetings is the exhibit made by the firms which manufacture physicians' supplies and medicines. At the annual sessions of the American Medical Association, the exhibit hall is well patronized. At the Atlantic City session abundant room is provided in the large entrance pavilion on Young's Pier. Nearby are the postoffice, the Registration Bureau, the Information Bureau, the meeting places of several of the sections, and the General Meetings. We give below brief mention of most of the firms who are represented in this exhibit.

W. D. Allison Company, Indianapolis—Spaces 44 and 45.

These well-known exhibitors at medical conventions will make their display this year at Atlantic City one of even greater value than usual. Several new appliances—their automatic table, improved cabinet and a new adjustable chair for oto-laryngologic specialists, and the Bihlmaier medical electric vibrator—will be shown for the first time. Every physician is naturally interested in seeing these latest additions to professional equipment.

American Ferment Company, Jersey City, N. J.—Space 61.

Here will be shown the well-known preparations of the vegetable ferments, caroid and bana-diastase (a diastasic preparation from the banana plant), in powder, tablets and liquid. The principal exhibit of the company will be a line of new pills, "pill triturates." It is claimed that the pills made by the "Mead Process" are more friable and more soluble than others. These qualities will be demonstrated at the booth.

American Peroxide and Chemical Company, New York—Space 54.

In this exhibit of peroxid of hydrogen, the manufacturers show their special product made by their own process, for which they claim superiority for the following reasons: absolutely non-explosive, no decomposition by reason of time or temperature, therefore absolute permanency and potency to the last drop; less acid than other preparations, consequently non-irritating. They will also show stearate of zinc in its many combinations, and a full line of proprietary and pharmaceutic products.

American Vibrator Company, Canton, Ohio—Space 97.

This firm will demonstrate the Tonjes aero-vibrant, a vibrator operated by compressed air. They claim it to be the only vibrator which truly vibrates and does not "jar" and "pound" the system. It can be operated with any air or nebulizer outfit. They will also show their air compressors which do not require air tanks. These are operated by hydraulic or electric power, and constantly supply air pressure and volume equal to the power used. No air tank being used, the air remains pure and fresh.

Ammonol Chemical Company, New York City—Space 60.

This firm has not a great variety of preparations, but they have much to say and much evidence to offer as to the value of the different preparations of ammonol. They will show this stimulant, heart regulator, antipyretic and analgesic, in combination with salicylic acid, and with bromids, with codein, quinin, etc., and will lay great stress on its value and safety in the conditions for which it is indicated.

D. Appleton & Co., New York—Space 7.

The exhibit of medical works published by D. Appleton & Co. is worth a visit. Particular attention is called to the following new books, published this year: Fox's "Diseases of the Eye"; Pearce's "Diseases of the Nervous System"; Beck's "Röntgen-Ray Diagnosis and Therapy"; Leube's "Medical Diagnosis"; Janeway's "Clinical Study of Blood Pressure in Medicine and Surgery"; Boas' "Diseases of the Intestines," new edition.

Armour & Co., Chicago—Spaces 80 and 81.

A complete line of the laboratory products of this firm will be shown, including pepsin, pancreatin, extract of red bone marrow, nutrient wine of beef peptone, thyroids, suprarenalin, suprarenalin solution, and other organo-therapeutic agents. Those in charge of the booth will pay particular attention to their suprarenalin solution. Soluble beef will also be shown and an opportunity will be given to visitors to sample it.

Bernstein Manufacturing Company, Philadelphia—Spaces 74 and 75.

This company will show examples of their entire line of goods, which includes metallic bedsteads, ward carriages, sterilizers, and other aseptic hospital furniture of great variety; operating tables, physicians' office tables and chairs, together with many other special devices for the equipment of physicians' offices and hospitals.

Frank S. Betz Company, Chicago—Spaces 57 to 59.

In the space occupied by the Frank S. Betz Company are shown hundreds of surgical instruments of all uses and varieties. A beautiful static machine, completely equipped, which the manufacturer claims will give a 25-inch spark, is to be given away to some one of the visitors at the exhibit. Mr. Betz will lay special stress on the quality and the reasonable prices of his instruments and machines.

James G. Biddle, Philadelphia—Spaces 87 and 90.

James G. Biddle, general sales agent for the Roentgen Manufacturing Company, will exhibit the latest type of heavy output *x*-ray coil constructed by his company—an 18-inch coil with electrolytic and self-starting mechanical interrupter operating on 110 volts direct current. The coil will deliver very heavy output, capable of the most rapid radiographic work. Mr. Biddle will also exhibit a very interesting portable coil, and other apparatus.

Bioplasm Company, New York City—Space 72.

Among the new things in materia medica, the Bioplasm Company exhibits a preparation from animal glands, under the name of "bioplasm," in several forms. They declare it to be a wide departure from all former glandular extracts and nuclein preparations, it more closely resembling the serums, as it evidently acts in the blood stream. They claim it has shown the remarkable property of rapidly increasing the scavenging and antitoxic elements of the blood, and are prepared to show strong clinical backing for the claim of bioplasm to the attention of the up-to-date practitioner.

P. Blakiston's Son & Co., Philadelphia—Space 16.

An attractive and very instructive exhibit of standard medical, dental, pharmaceutical, chemical and allied scientific books is made by this well-known firm of publishers and booksellers. In the binding of some of the more recent cloth books issued by this house, viz., Montgomery's Gynecology, Edgar's Obstetrics, Tyson's Practice, etc., an interesting departure has been made from the cut-and-dried styles in vogue for many years. The result is a volume of greatly increased attractiveness and distinguishableness. Another feature, too, is noted in the exhibit of this progressive house and that is the increase in half-morocco and the decrease in full sheep-bound books. The preference claim for the morocco binding is that it is more serviceable in every way and permits of a more richly and better and more durably bound book.

Bovinine Company, New York—Space 70.

The Bovinine Company's exhibit of their product is an excellent arrangement, and they claim that, as their connection throughout the world is only with physicians, their preparation should be investigated and its claims shown to be without basis or substantiated. Their agent, Mr. M. S. Smith, will be glad to talk with any physician who calls at his exhibit. He will furnish to those desiring them copies of the exhaustive work on "Hematherapy," which will be found of interest.

Churchill Chemical Company, New York—Space 86.

At the exhibit of the Churchill Chemical Company is shown pinagestin elixir, which they say is the only pharmaceutic product of pineapple juice on the market prepared exclusively for physicians' prescribing. They call attention to the remarkable proteid digesting power of pineapple juice, and to the fact that it will operate in an acid, neutral or even alkaline medium. Another product of this firm worthy of attention is Churchill's Viburnum Compound, in which the notoriously nauseating properties of its medicinal constituents are said to be completely disguised by their incorporation with a fragrant, spicy and most delightful combination of pure and non-toxic aromatics, thereby forming a compound pleasant, palatable and delectable to the taste.

Clark & Roberts, Indianapolis—Spaces 18 and 19.

Clark & Roberts intend making an exhibit of surgical furniture. This will be of especial interest to physicians, as the firm makes a specialty of high-grade furniture for physicians' offices and operating rooms. They are calling attention to the embodiment in their goods of all the latest designs and improvements in this line, as well as some very fine finishes, both in the white enamel and the grained enamel. They will show a line of surgical tables, instrument cabinets, etc.

F. A. Davis Company, Philadelphia—Space 64.

One of the book exhibits will be that of F. A. Davis Company, the publishers of Sajous' "Cyclopedia of Practical Medicine," Sajous' "Internal Secretions," etc., and numerous other unique and valuable works. They will have on exhibit Dr. Ball's new book, "Modern Ophthalmology," which they claim to be the most beautifully illustrated work of the kind published for many a decade. Attending members and visitors will find it of interest to examine this book and the many other splendid books by able writers recently issued by this house.

Denver Chemical Manufacturing Company, New York City—Space 62.

One of the popular booths will be that of antiphlogistine, the preparation which during the last few years has come so into prominence. The company will be represented at the Atlantic City session by Mr. W. W. Burgess, Mr. Paul Fleet, Mr. Thos. F. Moore and one or two other genial and popular representatives.

DeZeng Optical Company, Philadelphia—Space 53.

The DeZeng Optical Company will make a complete and handsome exhibition of their instruments in Space 53, near the outer end of the pier. They will make a special feature of the new DeZeng luminous ophthalmoscopes and retinoscopes which are attracting wide attention and which have been extensively advertised for some time past in THE JOURNAL. Practical demonstrations will be given daily of both of these instruments on living eyes, and every one is invited to witness them.

Electro-Surgical Instrument Company, Rochester, N. Y.—Spaces 55 and 56.

Here will be found on exhibit a full line of electrically lighted instruments, including among others the following: Bransford-Lewis' ureter cystoscope, Elsner's ureter cystoscope, Belfield's diagnostic cystoscope, Koch's urethrascope, Swinburne's posterior urethroscope, Tuttle's air dilating rectal tube, Beach's rectal tube, Cook and Pratt's rectal specula, Einhorn's esophagoscope and gastrodiaphane, Jackson's postnasal illuminator, Wishart's ophthalmodynamometer. They will also have a very complete display of electro-therapeutic apparatus.

E. Fougera & Co., New York City—Spaces 91 and 92.

E. Fougera & Co. display colchi-sal (colchicin-methyl-salicylate comp.), which is well established as a gout remedy, and betul-ol (methyl-oleo-salicylate comp.), for cutaneous exhibition in myalgias; kügloids of glycerophosphate of quinin dissolved in benzoates of eucalyptol and creosote, Huxley's syrups and tablets of the compound glycerophosphates, which they claim to be permanent and the most concentrated preparations on the market, and last, the new antiseptic salt, huxsal, which is a soluble salt, partially a chemical combination and partially a mechanical mixture of antiseptic materials, which, in 2 per cent. solution, they claim to be equal as a germicide to bichlorid of mercury.

Fritzsche Brothers, New York City—Space 22.

The firm of Fritzsche Brothers will make an exhibit of photographs of the *Graminaceæ*, whose pollen is concerned in the causation of hay fever, and specimens of the pollen from which they prepare "pollantin." This pollantin is the antitoxin serum for hay fever, prepared under the direction of Prof. Dunbar.

R. W. Gardner, New York City—Spaces 68 and 69.

The firm of R. W. Gardner will exhibit their well-known perfected products. The original syr. Gardner's syrup hydriodic acid (hydrogen iodid), originated by Mr. Gardner in 1878, needs no comment. The original Gardner's C. P. ammonium hypophosphite was brought forward by Mr. Gardner in 1897. The original pil. hypo-quinidol (Gardner), first introduced to the profession in May, 1898, is a non-toxic quinin, effective in half the dose of the sulphate. It is followed by no tinnitus or shock.

Gleason Grape Juice Company, Fredonia, N. Y.—Space 83.

An exhibit and demonstration of the unfermented fruit and grape juices, grape juice and apple juice, which this company prepares, will be here shown. They claim that the physician should be able to depend on the purity of these products, as they are made from finest Concord grapes and selected handpicked apples. The juices are stored in glass and sold only in glass and they offer a forfeit of one hundred dollars for every bottle of their juice found to contain preservatives or adulterations of any kind.

Globe Manufacturing Company, Battle Creek, Mich.—Space 63.

Several beautiful nebulizing outfits will be seen here under the banner "Globe Nebulizers," including multinebulizers on individual bases, ready to be attached to air supply, elaborate table outfits, with multinebulizers, receivers, metal and oak tables, with plate-glass tops, all finished in the style peculiar to their apparatus, a handsome shining gold enamel for the receivers, and combination of green and gold for metal tables. Their line of hand nebulizers will also be displayed, and altogether their exhibit will merit a call.

F. A. Hardy & Co., Chicago—Space A.

These wholesale opticians and makers of eye, ear, nose and throat surgical instruments will have their exhibit at the Steel Pier, the place of meeting for the Section on Ophthalmology and the Section on Otology and Laryngology. They will exhibit a line of high-grade ophthalmologic apparatus and surgical instruments of the latest and most improved models and will show a number of new specialties. The exhibit will be under the personal supervision of Mr. Kratzmueller and will prove to be of great interest and advantage to the oculist and to the ear, nose and throat surgeon.

Horlick's Food Company, Racine, Wis.—Spaces 76 and 77.

Horlick's Food Company exhibit their unique product, Horlick's malted milk, so widely known as a nutrient for infants and invalids. Pure milk is thus administered very efficiently, either for the immature digestion of infants or the weakened assimilative powers of the adult. The delicious cold beverages and malted milk ice cream served during the session give the physician an opportunity to judge of its value as a nutrient and refrigerant in fever cases.

Imperial Granum Company, New York City—Space 73.

The exhibit of "Imperial Granum" will aim to show the usefulness and palatableness of this preparation for the feeding of infants and invalids. This is one of the widely used foods for feeding infants and for use in stomach affections, and the representatives in charge of this exhibit will be ready to describe the preparation of "Imperial Granum" to all interested.

Keasbey & Mattison Company, Ambler—Space 26.

These extensive manufacturers of granular effervescent salts will exhibit alkalithia and phosphate and benzoate of soda. They will emphasize that alkalithia is an old and thoroughly tested combination of uric acid solvents, and that it constitutes a very efficient treatment for gout, rheumatism and such manifestations of lithemia as eczema, pruritus, mental perversions, migraine, asthma and hay fever. They will call attention to the preparation, phosphate and benzoate of soda, as an ideal hepatic stimulant and intestinal antiseptic.

W. T. Keener & Co., Chicago—Space 9.

The specialty of this house is supplying books of all publishers. Their exhibit will contain some of the important new books of American, English, French and German medical publishers. Perhaps some of the most important new books are: Leaf's translation of the "Anatomy of the Lymphatic System," from Poirer and Charpy's treatise, which has been called the best text on anatomy in any language; Gould's "Surgical Diagnosis," and Dr. Burney Yeo's new work on "Climates and Mineral Springs."

Keystone Electric Company, Philadelphia—Spaces 17 to 20.

They will have on exhibit the following: X-ray apparatus; galvanic, faradic and cautery batteries; wall cabinets, table plates, Finsen lights, vibratory massage apparatus, current controllers, motor dynamos, diagnostic lamp outfits, eye and ear oscillators, eye magnets, electrodes, air compressors, etc.

Kress & Owen, New York City—Space 100.

Among the exhibits we find glyco-thymoline, on which the company lays great stress as representing the application of scientific principles to the formulating of a preparation which harmonizes with the secretions of the tissues treated. Kress & Owen Company will be represented with an exhibit where glyco-thymoline can be obtained by members of the Association.

Lea Brothers & Co., Philadelphia—Spaces 99 to 101.

Lea Brothers & Co. have contributed a most attractive exhibit of their standard publications. Perhaps the most important is the new work on surgery by v. Bergmann, etc., of which the American edition is edited by Prof. William T. Bull. Other new and notable volumes are "Starr on Nervous Diseases," "Roger on Infectious Diseases," "Brewer's Surgery," "Morrow on Social Diseases," "Findley's Gynecological Diagnosis," and the revised edition of "Musser's Diagnosis," "Simon's Clinical Diagnosis," "Dunglison's Dictionary," "Ewing on the Blood" and "Hyde and Montgomery on the Skin."

Charles Lentz & Sons, Philadelphia—Space 66.

This firm will show a full line of surgical instruments, of their own well-known manufacture, for which they claim special superiority. One of their claims is that their cutting instruments undergo such processes in making as render them tenacious of a keen edge. They will show a complete outfit of Dr. Andrew J. Downes' latest electrothermic hemostatic instruments, and their formaldehyd-gas disinfector.

J. B. Lippincott Company, Philadelphia—Space 36.

This exhibit will present, in a large oak case, the ornamental electrical devices displaying the date of the foundation of the house, 1792, and the year of the exhibit. This case will contain some one hundred volumes, embracing the most recent and important of Lippincott's medical and surgical works. It is to be arranged for the convenience of those who would personally examine the publications in detail and offers an excellent illustration of the fine and substantial work in binding books for which the company is noted.

Londonderry Lithia Spring Water Company, Nashua, N. H.—Space 71.

The Londonderry Lithia Spring Water Company will exhibit its universally known water in its standard sized bottles (still and effervescent). Members of the American Medical Association and families will be served with Londonderry gratuitously at the exhibit booth. The company calls attention to Londonderry as having been officially designated as the exclusive mineral water to be served, gratis, at all the smokers which occur. Handsome souvenirs will be given physicians and ladies by the Londonderry Company.

Malt-Diastase Company, New York City—Space 30.

The Malt-Diastase Company will exhibit their highly diastasic nutrients, maltzyme (plain); maltzyme with codliver oil; maltzyme with cascara sagrada; maltzyme with hypophosphites; maltzyme with iron, quinia and strychnia; maltzyme with iron, and maltsanta (maltzyme with yerba santa in tablet form). The representatives will try to make it worth while for physicians to visit this booth and form an acquaintance with these products. They declare that there is no better example of the high quality work done by legitimate manufacturers than maltzyme.

The Maltine Company, New York City—Space 79.

The various maltine preparations will make up the bulk of this exhibit. These preparations include various medicaments for various conditions, all with the basis of maltine. They will also show neoferrum, the new iron, explaining the manner of manufacture and showing the crude materials from which this therapeutic agent is prepared.

McKesson & Robbins, New York City—Spaces 48 and 49.

A new dentifrice, called calox, is a feature of this exhibit, the introduction of which, they claim, marks an era in the history of dentifrices. Calox is described as an oxygenated tooth powder which, when brought in contact with the fluids of the mouth, liberates oxygen as does hydrogen dioxid, sterilizing the mouth as well as cleaning the teeth. It unites the triple rôle of tooth powder, mouth wash and antacid. They also exhibit natrozone, pyrozone, the McKesson & Robbins nose cup for nasal lavage and the McKesson & Robbins toilet salt.

E. B. Meyrowitz, New York City—Space B.

The exhibit of E. B. Meyrowitz will include a complete line of eye, ear, nose and throat instruments, ophthalmologic and electric apparatus. Many new instruments will be shown, among them patterns of instruments devised by European specialists, and exhibited in this country for the first time. This exhibit will be shown in a separate room on the Steel Pier, and a cordial invitation to visit it is extended to all interested.

Nelson Scientific Instrument Company, Chicago—Space 84.

This firm, formerly known as N. O. Nelson & Co., manufacturers of static machines, will exhibit a machine of a new design. Mr. N. O. Nelson will be there personally to explain the merits of the apparatus, and will emphasize that the Nelson Scientific Instrument Company is making an effort to uphold the standard of static machines, believing that the medical profession do not want a cheap static machine, for such would be an expensive investment.

The Norwich Pharmacal Company, Norwich, N. Y.—Space 50.

The Norwich Pharmacal Company exhibits unguentine, of course. This is, perhaps, their best-known specialty; but, having for 20 years been extensive makers of standard pharmaceuticals, they also display pills, tablets, effervescent salts, elixirs, etc. Among the specialties are: Zemacol, a new animal derivative; unguentine spray, the latest unguentine adjunct; and sal tonique, their new effervescent tonic aperient. Their perfected antiseptic thermometer case will especially interest physicians. The first completed instruments made from the new model will be shown and demonstrated. Aluminum medals are to be used as souvenirs.

Oakland Chemical Company, New York City—Space 29.

This exhibit will consist of a display of dioxogen. This solution of H_2O_2, 3 per cent., is the only pharmaceutic made by the company. As an illustration of the tendency toward specializing it is instructive, for, while there is nothing secret about the process of manufacture, the company has devoted its entire attention toward developing improved methods and perfecting details, with the result of a steadily increasing demand for its goods.

Philadelphia Casualty Company, Philadelphia—Space 96.

A number of competent men will exhibit and explain the scope and protection of this company's professional accident policy. This Pennsylvania corporation, with assets exceeding $750,000, claims to issue the only policy ever written that provides absolutely full indemnity for death or disability from septicemia or septic infection, without reference to the circumstances of simultaneous wound and infection. The company will also demonstrate the utility of its malpractice insurance policy, and the special features not to be found in other policies of the kind.

Physicians' Standard Supply Company, Philadelphia—Space 5.

This company manufactures nebulizers, vaporizers, douches, air pumps, nebulizing fluids (for nose, ear, throat and lungs), spirometers, rubber goods, and tablets. A special feature of their exhibit will be the unique hay-fever douche, to be presented to each physician who will call for it. The perfection vaginal douche is their latest and most improved syringe, now being widely introduced and deservedly popular. The woman's monthly protector will be among their new outfits at the exhibit.

Henry B. Platt, New York City—Space 73.

This exhibit will be devoted to "Platt's Chlorides," the odorless disinfectant. The value of this liquid for all the purposes for which a disinfectant is used will be dilated on by the representatives in charge.

Rebman Company, New York City—Space 98.

At Stand 98 this company will exhibit all their recent publications. They desire to call particular attention to Jacobi's "Portfolio of Dermochromes," published in two volumes, and to their display of plates from that work, showing the remarkable results produced by a recently invented four-color process; also Freund's "Radiotherapy" and "Health and Disease in Relation to Marriage,' by various eminent German authorities, just published.

Rigaud & Chapoteaut, Paris, France—Spaces 91 and 92.

Rigaud & Chapoteaut are still pushing cypridol, lecithin, morrhuol creosote, strontium iodid, bromid and lactate, apiolin and cerevisin, which have been so thoroughly advertised that it is unnecessary to add anything here. They will give especial attention to their new product, glycogen. They state that when glycogen is given on an empty stomach it appears to increase vitality, steady the heart and to distinctly act as a prophylactic, antitoxic, having bactericidal properties, beside controlling diabetes and albuminuria.

Rochester Surgical Appliance Company, Rochester, N. Y.—Space 82.

A very complete line of electrically illuminated instruments and sundry appliances will be shown: Cystoscopes, urethrascopes, current controllers, vaginal specula, rectal specula, eye magnets, galvanic, faradic and cautery batteries, cold miniature lamps, etc. This company calls attention to the care and skill with which their instruments are made and to the indorsements of many eminent specialists as well as hundreds of general practitioners. Their exhibit should prove of interest to every one who attends the convention.

W. B. Saunders & Company, Philadelphia—Space 78.

Directly facing the main entrance of the large room in which the exhibit is held, Space 78 is occupied by an excellent display of books shown by W. B. Saunders & Co., the prominent medical book publishers of Philadelphia, New York, and London. The display will certainly be a most attractive one and will give a very good idea of the high character of the Saunders publications, both as to literary superiority and mechanical excellence. The exhibit will be in charge of Dr. J. A. Heffernan and Mr. O. M. Smith, who will take pains to give every physician an opportunity to see such books as he is not already familiar with.

Schieffelin & Co., New York City—Spaces 68 and 69.

A general line of chemical and pharmaceutical products will be here shown, with a special display of their soluble coated pills, which make a very handsome appearance, the transparency of the coating showing the exact coloring of the different masses. As usual, especial attention will be given to hemoquinin, antimalarial and reconstructive; uriform, urinary antiseptic; heromal and heroterpin, their specialties.

Smith, Kline & French Company, Philadelphia—Space 27.

In the Smith, Kline & French Company's exhibit space will be shown both Eskay's food and Eskay's neurophosphates. Their representatives will give all visiting physicians as much information and demonstration as possible. Samples of these two products in particular, as well as descriptive printing matter and souvenirs, will be handed to all those showing sufficient interest to take them home and to give the products a trial. They expect to serve Eskay's food to those wishing to test its nutrient properties as well as its palatability.

Arthur H. Thomas Company, Philadelphia—Space 67.

This exhibit is devoted principally to microscopes and clinical apparatus for physicians' office use in the examination of blood, urine, sputum, etc. Particular attention will be called to samples of museum jars for pathologic laboratories, incubators, sterilizers, microtomes and projection microscopes. The new Stanton blood pressure indicator will be demonstrated, as will also the new physicians' portable microscope in compact case carrying mechanical stage, hemoglobin apparatus, hemacytometer, etc. A skilled attendant will be on hand to demonstrate these specialties.

The Trommer Company, Fremont, Ohio—Space 25.

The exhibit of the Trommer Company will consist of Trommer extract of malt and combinations, and palmiacol, the new derivative of guaiacol. Samples of these will be for gratuitous distribution and the company cordially invites the medical profession to call and make their wants known in this connection. The exhibit will be in charge of the veteran representative, Dr. Paul Plessner, who is vice-president of the Trommer Company; other well-known representatives will assist.

Vibrator Instrument Company, Chattanooga, Tenn.—Space 39.

In this space of the exhibit several Chattanooga vibrators will be on exhibition; also a treating table, and any physician so desiring will be given a treatment by the demonstrators in charge. Complete catalogues and literature on the subject of mechanical vibratory stimulation and the Chattanooga vibrator will be on hand there for distribution. This vibrator is sold to physicians only.

R. V. Wagner & Co., Chicago—Spaces 13 and 14.

R. V. Wagner & Co.'s exhibit will be of unusual interest, as they will have a working demonstration of the new Wagner adjustable focus tube. They call attention to this as the only tube not focused by guess. It is adjusted to a perfect focus while in operation. The magnetic device is very simple, and those interested in *x*-ray work will obtain information of practical value. They will also exhibit a new type of their mica plate static machine adapted to both *x*-ray and high-frequency work.

Henry K. Wampole & Co., Philadelphia—Space 1.

The preparations which the above company will exhibit include their lines of pills, tablets and elixirs and the specialties on which they place so much emphasis for elegance of preparation, potency of medicinal agents and accuracy of composition. Among these will be Wampole's tasteless preparation of the extract of cod-liver oil, formolid (the antiseptic solution), liquid wheat, hemogen, saw palmetto wine, syrup of hydriodic acid, etc.

Wm. R. Warner & Co., Philadelphia—Space 85.

This exhibit will consist of a general variety of pharmaceuticals, including the prominent specialties of the company, among which we may name ingluvin, lithia water tablets, elixir salicylic comp., liquid pancreopepsin and a number of others. Of special interest to the practitioner is the granular effervescent calcium carbonate, also the two recipes granular effervescent formin comp., A and B.

Welch Grape Juice Company, Westfield, N. Y.—Spaces 88 and 89.

This display of Welch's grape juice will be pleasing to the physician, for the value of grape juice for the sick is well recognized. This firm claims absolute purity, the juice being sterilized and then hermetically sealed, so that there is no preservative, no alcohol, but only the pure juice of the grape. They expect to dispense the ice cold juice to all physicians.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A Text-Book of Operative Surgery, Covering the Surgical Anatomy and Operative Technic Involved in the Operations of General Surgery. Written for Students and Practitioners. By Warren Stone Bickham, Phar.M., M.D., Assistant Instructor in Operative Surgery, College of Physicians and Surgeons, New York. Second Edition. With 559 Illustrations. Cloth. Pp. 984. Price, $6.00 net. Philadelphia, New York and London: W. B. Saunders & Co. 1904.

Preliminary Bulletin on Insects of the Cacao, Prepared Especially for the Benefit of Farmers. By Charles S. Banks, Entomologist, Bureau Government Laboratories. 1904, No. 11. Department of the Interior. Bureau of Government Laboratories. Biological Laboratory, Entomological Division, Bulletin No. 1. Paper. Pp. 58. Manila: Bureau of Public Printing. 1904.

Diseases of the Intestines. By Dr. I. Boas, Specialist for Gastrointestinal Diseases in Berlin. Second Revised and Enlarged American Edition, Translated by Permission from the German Edition, with Special Notations and Additions. By Seymour Basch, M.D., New York City. With 48 Illustrations. Cloth. Pp. 600. Price, $5.00. New York and London: D. Appleton & Co. 1904.

Jahresbericht über die Fortschritte in der Lehre von den Pathogenen Mikroorganismen unfassend Bacterien, Pilze und Protozoën unter Mitwirkung von Fachgenossen bearbeitet und herausgegeben von Dr. med. P. von Baumgarten, und Dr. med. F. Tangl. Achtzehnter Jahrgang. 1902. Erste Abtheilung. Paper. Pp. 368. Leipsic: Verlag von S. Hirzel. 1904.

The Closure of Laparotomy Wounds, as Practiced in Germany and Austria. Including Detailed Methods and Views Communicated by Over Fifty Leading Surgeons. Edited and Translated by Walter H. Swaffield, F.R.C.S., Ed., M.D. Ed., Fellow of the Obstetrical Society of London. Cloth. Pp. 72. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1904.

Adolescence, Its Psychology and Its Relations to Physiology, Anthropology, Sociology, Sex, Crime, Religion and Education. By G. Stanley Hall, Ph.D., LL.D., President of Clark University and Professor of Psychology and Pedagogy. Vols. I and II. Cloth. Pp. 590 and 784 respectively. Price. $7.50. New York: D. Appleton & Co. 1904.

The Mothers' Manual. A Month by Month Guide for Young Mothers. By Emelyn Lincoln Coolidge, M.D., Visiting Physician of the Out-patient Department of the Babies' Hospital, New York. Illustrated. Cloth. Pp. 262. Price, $1.00 net. New York: A. S. Barnes & Co. 1904.

Annual Report of the Surgeon General of the Public Health and Marine-Hospital Service of the United States. For the Fiscal Year 1903. Paper. Pp. 572. Washington: Government Printing Office. 1904.

Twenty-Third Annual Meeting of the Hamot Hospital Association, with Report of Managers and Officers, 1903. Paper. Pp. 67. Erie, Pa.: Herald Printing and Publishing Co. 1904.

Transactions of the Fifth Annual Meeting, the Rocky Mountain Interstate Medical Association. Cloth. Pp. 132. Salt Lake City, Utah, Sept. 1 and 2. 1903.

VOL. XLII. CHICAGO, ILLINOIS, JUNE 11, 1904. No. 24.

Address.

SOME ASPECTS OF MEDICAL EDUCATION.

PRESIDENT'S ADDRESS AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT ATLANTIC CITY, JUNE 7-10, 1904.

JOHN H. MUSSER, M.D.

PHILADELPHIA.

It is no trifling occasion that draws together from the uttermost parts of the country one-fifth of an organization of a profession that is taxed to its utmost in the prosecution of its duties. It is not with sounding trumpets and tinkling cymbals that from the sorrowing bedside—whether in the hovel of the poor or the palace of the rich—from the excitement of the operating room, from the stimulus of the hospital ward or the quiet but inspiring haunts of the laboratory this assembly gathers. That it is possible is a handsome tribute to the noble animus in which are embodied a spirit of inquiry, a thirst for knowledge, a longing for inspiration, a desire to uplift and to be uplifted that pervades the profession. The event is one that should be fraught with the dignity, the inspiration, one might almost say solemnity, befitting a symphonal march. For such animus, fellow members, we have just cause for self-congratulation.

It scarcely need be reiterated here that the spirit which pervades such a meeting is the outcome of that evolution which began with the introduction of precision in medicine. Just as soon as the art of medicine had for its foundation the science of medicine, the possibility of harmonious medical organization arose. When "rule of thumb" or intuition gave way to precision; idealism to realism; when speculation was displaced by fact; when, in short, inductive methods were employed and honest inquiry became the guiding star of action, then harmony could sit in council.

With medical, as with all organizations made up of human elements, it would be only human if not pervaded by the essence of science—truth. Hence with the latter wanting, jealousies and ambitions, self and selfishness would prevail to the end that the true object of organization—a fraternal spirit and conscientious seeking for truth—would be as a flickering flame. A little observation will show that that society, whether county, state or national, that does not have this true reason for its existence, for its guide of action, will be a failure. The reverse is also true that that organization which may be called unsuccessful and unhappy, of snarling men and backbiting colleagues can be labeled at once as without its true vocation, to the discredit of its members.

The great heights to which our organization is rapidly rising, precludes the activities of such as have self for their basis of action, so that each day we see more and more a noble rivalry of its members to do the utmost and the best for the organization; a healthful vieing of one another for its welfare. Self and selfishness are looked at askance; partisanship and faction, save for a common end—the welfare of the Association—are memories.

But, fellow members of the Association, at this the fifty-fifth session of our Association we have other causes for congratulation and felicitation. We are on the eve of a union of all the members of the profession in one harmonious organization, each individual of which is willing and proud to consider his fellow a gentleman until he is proved not to be, and not, as of yore, a knave until he is proved to be a saint. We are reaping the rewards of that untiring committee which gave to us this organization with which we now labor. We are prospering beyond measure and gathering a force scarcely to be estimated, in great part as a result of the untiring efforts of the apostle of organization—our McCormack. To say that thirty-four states have adopted the uniform plan of organization, and "that membership in the reorganized states has increased 400 per cent. and enthusiasm," writes our coadjutor, "tenfold more," is enough. We are standing out in our own manliness with the majesty that belongs thereto because of the sentiments expressed when our broadly inspired committee voiced the unanimity of feeling which belonged to the Association, in our principles of ethics. We are letting our light shine through the instrumentality of that genius of medical editors—our Simmons. From five thousand to thirty thousand in less than a decade is a statement of circulation which appals and at the same time arouses a feeling of pride and stimulates to further effort, increased all the more when we reflect that the scientific value of the articles in THE JOURNAL are surpassed by none of its contemporaries; its tone is emulated by all.

Such causes for congratulation bring to this Association greater responsibilities and weightier problems for solution. It is held to be the bounds of this address to indicate responsibilities, some trite and apparently trifling, others most weighty; to point out duties, many so grave and vast, beyond the powers of your official to justly define.

NECROLOGY.

Before passing to the task let us pause a moment and with due reverence take cognizance of our colleagues who have since our last meeting gone to the great majority. The Silent Reaper has been as rapacious as in the past, and more than fifteen hundred fell in his swath. He has spared neither the humble nor the great. The less conspicuous but just as potent laborers in the vineyard can say with the others: "I have fought a good fight, I have finished my course, I have kept the faith."

Of those who have been honored by this Association in the past we lost two ex-presidents, the hearty, rugged, yet withal gentle and kindly Donald MacLean, surgeon and teacher, and the urbane James Farquhar Hibbard, a revered general practitioner and teacher; two ex-vice-presidents in John Bates Johnson, one of the founders of the Association, a great practitioner, an honored teacher, and Isaac Newton Love, genial and magnetic. From the ranks we lost Edmund Andrews, scientist, pioneer in surgery and medical education in the west; George Julius Engelmann, obstetrician, scientist, litterateur, teacher, honored at home and abroad by membership in great organizations; James McFadden Gaston, pioneer in the surgical treatment of affections of the gall bladder and gall ducts, an esteemed practitioner; Franklin Staples, Hamilton Atchison West, Orpheus Everts, each obtained prominence and respect by force of character and natural attainments; Emile A. de Schweinitz, scientist and brilliant investigator, laboring not for his own renown but for that of his profession, passing away at the threshold of a most promising career; Frank Savary Pearce, untiring and enthusiastic, who had been expected to counsel with us this week.

HOUSE OF DELEGATES.

The conduct of business under the new constitution bodes success. The two years of trial have indicated that to the House of Delegates the greatest responsibilities fall. When its members consider the great power the American Medical Association will have for weal or woe in the future and that the great body gives that power almost unstintingly to the delegates, they should justly realize the honor and confidence bestowed on them. With such realization will come honest purpose and deliberate action. All the county and state organizations must appreciate the vast duties to be undertaken and the breadth of view, deliberation and wisdom essential to their correct performance, and consequently select from their number the best of their possessions. Let us as an organization see to it that honor and homage come to those who labor unceasingly in the House of Delegates.

NATIONAL LIFE.

It can be readily seen that an organization of the magnitude and with the object and the spirit of our Association must in justice to itself and duty to its country take part in its social and political life. In order that we can be in touch with such life it would be well for the Association to devote some time to the discussion of broad general topics. We have provided for discussions at this meeting, the advisability of which may be termed tentative. We feel they can be productive of great good, and if the experience on this occasion is the least encouraging, we would urge their continuance. We had hoped to have government officials take up matters pertaining to the relation of the medical profession to the executive, legislative and administrative departments of the government. The exigencies of politics forbade our obtaining the services of those worthy to address this body. All men of political affairs are too busy at this juncture. At other times we may learn with profit from our rulers and law makers. As arranged for this week, so in various parts of the country in which the meetings are held, broad topics of general interest, perhaps with local flavor, could be discussed. From those in the far west we might learn much of climate or how to conquer the plague or the medical aspect of "the yellow peril." The good judgment of the committee, or the President, can be relied on to select topics suitable to the occasion.

It is needless to refer to the demands that will be made on us by the nation in the future. You will learn through the representatives of the Army, the Navy and the Marine-Hospital Service what is expected of us. My distinguished predecessors, Reed, Keen and others, have pointed out our possibilities for good in the legislative halls of county, state and nation. We must have care never to be partisan or factional toward the weighty matters we will have to decide. We must realize that the power we have may be our undoing. We must realize that we are entering on dangerous ground and that it would better become us to be bidden rather than to intrude ourselves into such territory. Indeed, one may tremble not a little at the possibilities of our development in the wrong direction. So long, however, as we hold true to the spirit which comes out of devotion to science we need not fear.

THE SECTIONS.

The work in most of the sections the past few years bears favorable comparison with that of co-ordinated organizations throughout the country. To inflict discussion concerning them on this general meeting is, we realize, somewhat of a hardship. Your indulgence is craved, however, for through your medium alone can the sections be reached, while peradventure the work of these sections is fully as important as that of any branch of our Association work. If you will look into it you will find the rise of the Association came with the development of section work. To enhance the value of such work is, therefore, to uplift the organization. The present methods are worthy of trial for a few years just as we should not make haste in changing the new constitution. Regarding it, may we suggest thought along these lines?

1. The continuance of the secretary for a term of years.

2. The collaboration of sections so that one topic can be exhaustively considered at the meeting of the Association without repetition in other sections. For this purpose the officers of the sections should meet for consultation six or eight months before the annual meeting. We feel we did good work by having our distinguished chairmen and secretaries come together last October.

3. The division of the Association into two main sections for work in the mornings, that of (A) *medicine*, including pathology, diseases of children, nervous and mental diseases, materia medica, stomatology, cutaneous medicine and sanitary science; (B) *surgery*, including obstetrics, gynecology and the more closely related surgical specialties. The members interested in diseases of the eye or nose or throat could contribute to either section the result of any studies related to the respective section. The afternoons could be occupied by the specialized labor of the twelve sections now in existence.

Perhaps it might be thought better to have one morning, at the direction of the Section on Practice of Medicine, devoted to the discussion of general topics related to medicine, in which the entire Association could take part; another morning, at the direction of its secretary, to surgery; a third to the specialties; a fourth to sanitary science. The object is to secure the views of physician, surgeon and specialist on general topics. To suggest the subject of endarteritis is to call up at once the possibilities for the internist, the surgeon and the specialist.

4. The sections should take up and organize special international congresses when the time is ripe for such meetings. Thus an International Congress of Dermatology could be managed by the correlated section of this Association. With the patronage of the American

Medical Association any congress that could command such special energies and broad general support could not fail.

5. The section should name to the President a list of its members from which he could select, when asked, delegates to important national meetings or international congresses.

SANITARY SCIENCE.

The Section on Hygiene and Sanitary Science should receive greater support from the organization. It is the section which must bring us in closer touch with our national life. Through it and those devoted to it we ought to secure greater respect from the body politic, and hence more wholesome power for the welfare of the community. Through it the profession should learn to take greater interest in the work of sanitary officers throughout the country. The valuable address of Billings on "The Relation of Medical Science to Commerce" and that of Thompson on "The Economic Value of Medical Science" indicate the opportunities and responsibilities of the profession. The time has gone by when sanitary positions should be used for temporary sources of income and obtained by political means. Such offices are growing more and more vital to the public welfare. They have not been attractive because the rewards have not been commensurate with the responsibility and the labor demanded. They should, we will admit, if looked at from the proper viewpoint, grant large compensation and the occupant should be guaranteed tenure of office not subject to party exigencies but dependent on value received. The fault is partly ours that such is not the case. In but few medical schools is there a serious attempt to educate sanitarians, consequently the physicians who engage in sanitary science in an amateurish way do not give a *quid pro quo*. It does not pay a community to hire them. In one of the large cities of this country it has been impossible for the health authorities to get men who were competent to take up health matters, even though the city was prepared to pay fair salaries. Speculation need not run riot in estimating what would occur in a few years if our universities would give sound practical courses of a broad character, including some engineering, some economics and other features which would round out the man. In the preliminary and subsequently in the elective studies the student should not be tempted to go into the special lines of practice. He should have opportunity to go in for sanitary science and perhaps for government service in the Army, the Navy, or other departments. The communities would soon find the worth of men thus educated, and the demand, we would venture to predict, would outrun the supply. In proof of the former, we may cite the fine tribute given to Wende of Buffalo by the citizens, *en masse* and of one accord, for the work of self-sacrifice, of unselfishness and of worth as official of the health department. Our Association could as a body and in its constituent parts encourage the medical schools to make such training possible; they could educate the community to demand such services and insist that good compensation is to be allotted for it. The Section on Sanitary Science could take up this as one feature of their work.

But for a more grievous reason, the profession's attitude, there is public disrespect. Survival of the old dictum that a patient's woes are confidential, supports too often the attending physician in failing to realize his responsibility to the community while attending to the welfare of his client. For this, as well as too often for personal reasons, he readily connives with the patient to thwart civic authority, thereby endangering a community. Instead of aiding in securing respect for and obedience to the rules of his sanitary colleague he joins in opposing him. Candor must compel us to admit that too often he fears the advent of the health official may mean some disclosure of his own incapacity. It is fair to say the official on his part is often too ready to give advice, to sneer at diagnosis or rail at treatment. To inspire, therefore, wholesome respect toward these coworkers and establish an *esprit de corps* should be one of the educational prerogatives of this section. Were we to be called to account for duties undone, the sin of not fulfilling our obligation to the community in sanitary matters would doubtless be found the most conspicuous, the one most detrimental to its interests.

Again, if not too insistent, could not this section further educational exhibits in sanitary matters not unlike the superb exhibit last winter in Baltimore, conceived and conducted in the main by our present official of the Sanitary Section? The Association could not do better than issue a grant for the furtherance of this object.

THE SCIENTIFIC EXHIBIT.

It is gratifying to see the interest and success attendant on this new feature of section work. It is another tribute to the belief in the permanent tenure of office of an official when we have the good fortune to get a good one. Attention is particularly called to this exhibit to ask the Association and the other sections to look to the conduct of somewhat similar exhibits. The Section on Ophthalmology showed the possibilities at the time of the Helmholtz anniversaries. When a section takes up a subject let us not have the clinical, pathologic and therapeutic aspects alone discussed, but bibliographic and historic features brought out. Let such features be as national as possible. What a fine exhibition it would be to have in connection with, say typhoid fever, a loan collection of the pictures of authors and investigators, of the various editions of their works and of the material things with which they worked, illustrating the evolution of their knowledge of the subject. Who would not be thrilled by a picture of the wards of the old Pennsylvania Hospital where Gerhard worked, of the instruments or materials he worked with, how he lived and what he did; of the first editions of his works, indeed of the manuscript of them? We must confess to a quiver of delight, mingled with reverence, when permitted to handle the manuscript on which Stillé inscribed his communication to the Paris Society. This is not the time or place to indulge in a homily on the value of such exhibits, agreeable though it might be. Through them, as of biography and sculpture and painting ,we keep in touch with our history. Foster efforts in these directions, gentlemen of the Association, grant liberally to sections their small demands on you, to the end that you will be stimulating the best instincts in our profession.

THE ASSOCIATION OF LIBRARIANS.

We are not far amiss when we call attention to an organization which in a quiet, unobtrusive way is bringing together the members of the profession on a common ground, where tares do not spring up and thistles do not blossom, but instead in an atmosphere clear, refreshing, invigorating. Jealousies do not thrive in libaries; books soften ambitions. No stronger, more liberal friendships can develop than those that come to book lovers. We owe a debt of gratitude to the Li-kind and unjust to the students by having them think it is not essential. Medical colleges that pass off a hospital training for one that is not truly such, fake their students. The student who pays well for his training has the right to demand such as to fit him for immediate action.

It is not the fault of the medical school alone that he can not get it. The public that cries out when there is mistake in diagnosis, fault in treatment, and that shakes its head at the deficient education of our students, must share the blame with the medical school. The public admits that its individual members may at any moment almost be at the mercy of a half-educated physician. It is not necessary to recount, for it is well known, how on land or sea, by day or night, some event may arise in an individual life, the care of which may mean life or death. Even with this knowledge they withhold means to relieve themselves. They admit the necessity of a hospital training. But they, and particularly the public in control of hospitals not used for teaching, say each medical college should have its teaching hospital. They do not appreciate that to give an education which involves a hospital course would require an expenditure of $500 a year for four years by each student. It has been estimated that the cost of maintaining a plant and paying salaries sufficiently large to accommodate 600 students would require the above outlay by each student. Unfortunately, it is impossible to expect students to pay such figures, as it would render entrance into the profession almost prohibitive. It is manifestly impossible, as medical schools are constituted now, to educate all the students of the land properly. Hospital training can not be given except by a few favored institutions, because the doors of hospitals are closed either by the governing body of the hospital or by the teachers in the medical schools.

We believe, personally, if a decree should be issued that no medical school, including its hospital, should exist except on the fees derived from students, but little hardship would follow. The lessened supply of students would increase the demands on the practitioner, so that larger returns would follow. The poor student would sacrifice and strive to get a degree, knowing then he had a good asset. A diminution in number and an increase in quality is demanded alike by the public and the profession. Such diminution in number would mean that the student would get back his investment quicker and in larger amount than at present, hence good men would be attracted. If we could abolish sentiment for sense and educate accordingly, there might be betterment all around. As it is now, medical students receive part of their education through the bounty of the state or the charity of the public, as such education can only be given in endowed institutions. The public is taxed so that the prospective physician can make a living. Is it right that it should be? Perhaps a mechanic should demand such right to make his son a good workman. We must all admit it is the duty of the state to educate the youth, so that good citizenship is maintained; we can question whether the state should educate the members to obtain a livelihood.

With the same indifference that the public views an epidemic's march they allow hospitals that are engaged in teaching to suffer for the want of funds. Moreover, they close their doors to the advent of teaching in the hospitals under their control. We must admit those who do not appreciate the true function of a hospital have some ground for their contention. Ruled by sentiment chiefly, unfortunately an impracticable master, they sympathize with the patient who still harbors the belief of old that the medical student is one of a class that prowl about not unlike harpies. The public does not realize the difference in the student of to-day and the student of tradition. We can not hold to account the governing body of the hospital who has the point of view that it is harmful to a sick person to have them under the surveillance of an alleged student rabble. We must admit some patients become alarmed, particularly in institutions where they know they will have the sympathy of the governing body. An analysis of motive will show that the usual patient who will not allow a judicious amount of clinical demonstration when the sense of delicacy is not offended, is truly selfish, in that there is prevented that increase of knowledge and development of skill whereby suffering of others may be alleviated. A little encouragement from the officials would allay alarm on the part of the patient. The desire to help others is infectious, and when one yields in a ward, others vie in the work.

The truth of the matter is that in hospitals in which teaching is carried on, rarely, if ever, do the patients complain. Indeed, it is the experience of those teaching institutions that judiciously conducted instruction is appreciated by the patient. In one hospital we might name most of the inmates are pay patients, giving $7 a week willingly, because they know they are buying the services of the best practitioners in the land—the teachers of medicine—which service they could not get at tenfold the figure. The fact that teaching hospitals are overcrowded, not by the poor alone, but by people independent of charity, shows that clinical instruction is not a bugbear. If the governing boards would know that while a few patients might be alarmed, on the whole most of them would be gratified by the attention paid them, and their sense of rectitude and manliness appealed to by the satisfaction that they are doing some good in enlightening students, so that others could be relieved; that their administration would be stimulated to do work beyond criticism; that the nurses would be aroused to better activity while under the observation of those not connected with the hospital; that the internes would do their very best to have most complete studies of the case, and finally, that the chief in attendance, compelled to do his best at the risk of his reputation, they would gladly open their doors, even at the discomfort of the few, but to the advantage of the many. In short, the hospital should have teaching not to oblige the medical school, but for its own survival and regeneration. The benefits the student derives by the object lesson of an orderly hospital can not be estimated. Will not every member of a hospital board admit that his own character, his own sympathies, have been benefited by his connection with the hospital, even though, perhaps, he has not the advantage of an impressionable age? Can he not see, therefore, how the youthful student can be influenced in thought and character and feeling? He can not lightly toss aside this responsibility, nor even hide it by putting the onus of medical education on the teaching hospital. Every dollar endowing a non-teaching hospital robs the teaching hospital which is engaged in this larger duty.

It is true a class who are compelled to have hospital attention may not sympathize with this feeling. How can we obtain the confidence of this class? Let us organize such association of prominent people in our teaching centers who will agree to have any operation, any feature of disease witnessed by medical students, at the judgment of their attending physician. It would be well if the individuals of such an organization would agree, first, to undergo hospital treatment; second, to be the object of observation by students; third, to have an autopsy performed in case of untimely end. Such association would rob hospitals of their terror and teaching of its dread. No one can deny that on the whole the public would be benefited from whatsoever point of view we look at it. Indeed, the public ought to learn that disease is an enemy to themselves and their country. Just as we make sacrifices in time of national warfare, so we should be willing to make sacrifices in the daily battle for life. Just as aristocrat and plebeian, landlord and tenant, fight side by side in the former, so they should array in solid phalanx in the latter.

But there are hospitals willing to admit students, and yet the privilege is not availed of. This arises because the teaching force of the medical college is not willing to sink its personality and allow the student to go wheresoever he will for his instruction. Courage and some sacrifice is required perhaps. But, when one thinks of the mighty opportunity and the frightful waste, it is saddening. Every hospital should be a school. The fourth year should be so arranged that the student could avail himself of the advantages of hospitals in the immediate vicinity. Let each teaching body have the student understand what he must see and do, and trust you the true student will see it at the best place and with the best men. He must be accountable, of course, with a rigidity that means the exact acquirement of knowledge. To this end the first two years could be well spent in the properly equipped laboratory university, whether in town or country, the third in the authorized hospital of the school, the fourth in extramural hospital work.

Is it not anomalous that the hospital boards give to the nurses who are to act as aids to the physician the highest opportunities, and yet deny it to those who are to give orders to the nurses? This, of course, arises because training schools are the product of modern thought and have not been trammeled by tradition.

But all this talk of the primary education avails but little if we do not see to it ourselves that education is continuous; that from the day of our graduation, forwards, we do naught but toil, toil, toil. It should go without saying, as a mere business proposition, that unless we unceasingly labor but little of the fruits do we pluck. It is demonstrated in a practical manner, for when we look about us and find the methods of those of our brethren whose labors are not in vain each one bears the scent of midnight oil.

The development of post-graduate schools, the growth of libraries, the groans of the printing press, the enthusiasm of medical societies, all testify to the spirit of persistent self-education that is abroad. It is not for me to urge further the importance of each of us taking from time to time months for study and reflection. Every active doctor should have his sabbatical year. We dare say, extended observations would uphold that in income a gain is one hundredfold for each dollar invested in educational outings, and for every hour thus employed, ten is added to life. To finance a medical man from first to last successfully, we dare say spend all net earnings of the first five years on self-education; 25 per cent. of each five years for further education; after ten years, 10 per cent. of the annual net earnings for an assistant, continuing the 25 per cent. investment each five years. Health, happiness, increased usefulness to the community—a success which never comes from eccentricity, equal to doubling capital every ten years, would follow. To this must be added the great mental satisfaction of a more clairvoyant vision in the prosecution of his daily duties, the inspiration that comes from the doing of things, the stimulation that arises from the solving of problems.

In the course of our work it is necessary for us to halt from time to time and review. Few of us are they who will not find as our days grow fuller an unconscious tendency to slight our work, to become slipshod, to hurry over matters. It is partly an evidence of overwork. The post-graduate school is the salvation. No obstacle can withstand the continuity of drill, which the earnest of us keep in action. If, to continue the imposition, asked what element of character is perhaps lacking to the greatest detriment to the profession and public, we possibly, one and all, would say courage. This is seen in the hesitancy which members of the profession show in giving an opinion, in advising an operation and in asking for an autopsy. How much confidence is destroyed by the want of free, frank avowal of the physician that he does not know on the one hand, or of clear, precise statement of his judgment concerning a case on the other! The greatest success in life is confidence. How many lives are lost by the worker in internal medicine not advising early and unequivocally an operation for fear he might be wrong in his diagnosis! And how many more are lost because the surgeon lacks courage to do, either because he fears the patient may die and his record be marred, or because he may operate when it is not necessary! We must admit we have had some operations done when they were not required, but let it be said to the credit of modern surgery, we have never seen an operation of such character performed by the right man that did any harm to the patient. On the other hand, the resort to operative procedures early, and in cases that even yet are not considered of surgical relief, has saved lives and lessened suffering to a degree that far overbalances the now and then futile measure. It may be assumed, without contradiction, that every case of bad appendicitis that happens to get well without surgical relief has in its wake three to five that die for the want of an operation. In other words, the pernicious influence of a surgical case that recovers without operation is evident in creating the hope that other cases demanding operation might get well without it.

And the man who does not want an autopsy—not only the centers of courage need stimulation, but too often the entire medical storehouse needs refitting. Something, best known to the physician himself, we trust, is lacking in the one who treats an obscure case for a day, six days, six weeks, and then does not want an autopsy. If true to himself, true to the demands of his profession, courage will not fail him. In our mental and physical round-up, we must see to it that courage is given a new backbone from time to time.

But, fellow members of the Association, not alone as members of this organization may we indulge in self-congratulation, but as members of a profession whose limitation knows no bounds, we may join in felicitation. Neither language, nor creed, nor country fetters our profession's munificent sway. The thoughts of Ehrlich in Frankfurt, of our own Welch or Councilman, of Kitasato in Japan, are correlated. The knife of Mayo in America, of Robson in London, of Kocher in Berne contributes to the relief of suffering in far Cathay. The founts of Lister's genius and Pasteur's divine inspiration bring countless blessings to England, to India, to France and to Africa. What a stimulus it is to realize that, howsoever small the contribution of the humblest of us may be, its impulse will be felt in climes near and far and ages present and remote! What awe can not but overtake us when we consider each heart throb we study entwines us to Harvey of two centuries ago; with every percussion tone reverberates the sound of Laennec's voice of a century; with each vaccine inoculation, the simple observation and reasoning of Jenner to stimulate our question and deductions!

We rejoice together and cherish our history, by the warp and woof of which we are woven to the past. What heritage for us and our children! Dead must be the soul that wearies of communion with the spirits of the past; deep must be its slumber on which falls the thought of centuries; lethargic its activities that are aroused not by the deeds of heroic men! "Honor and fortune exist to him who always recognizes the neighborhood of the great, always feels himself in the presence of high causes." We worship together our science, devotion to which brings forth character, smothers egotism, levels pretension, drives out solitude, develops such loftiness of thought which can see that "against all appearances the nature of things works for truth and right forever." Of our art, let us see to it that when the final summons comes it can be said of us, "Greater love hath no man than this, that a man lay down his life for his friends."

Orations.

PROGNOSIS; ITS THEORY AND PRACTICE.

ORATION ON MEDICINE AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT ATLANTIC CITY, JUNE 7 TO 10, 1904.

GEORGE DOCK, M.D.
ANN ARBOR, MICH.

The topic I have ventured to bring before you is "Prognosis; Its Theory and Practice." As a text, let me quote from the oldest work we have on this subject,[1] which, though old, still has the freshness and modernism that genius gives to human productions:

> It appears to me [said the Father of Medicine] a most excellent thing for the physician to cultivate prognosis; for by foreseeing and foretelling, in the presence of the sick, the present, the past and the future, and explaining the omissions which patients have been guilty of, he will be the more readily believed to be acquainted with the circumstances of the sick; so that men will have confidence to entrust themselves to such a physician. And he will manage the cure best who has foreseen what is to happen from the present state of matters. For it is impossible to make all the sick well. This indeed would have been better than to be able to foretell what is going to happen; but since men die, some even before calling the physician, from the violence of the disease, and some die immediately after calling him, having lived perhaps only one day or a little longer, and before the physician could bring his art to counteract the disease; it therefore becomes necessary to know the nature of such affections, how far they are above the powers of the constitution. Thus a man will be the more esteemed to be a good physician, for he will be the better able to treat those aright who can be saved, from having long anticipated everything, and by seeing and announcing beforehand those who will live and those who will die, he will thus escape censure.

In this Hippocrates describes the essential importance of prognosis to the patient and the physician in relation to treatment. Besides this, prognosis is often important to relatives and dependents, not merely for reasons of sentiment, but in order to protect property and prevent unhappiness and destitution that would be as painful for the patient to contemplate as for the others to suffer. There is another aspect not present in the time of Hippocrates—giving the patient an opportunity to prepare himself for the anticipated life beyond the grave. In many cases, too, prognosis may have important bearings on political parties or for the commonwealth.

The patient very often ignores these needs. If he asks for anything, it is usually either the name of the disease or that of the medicine the physician intends to use. He really understands as little of the significance of the name as he does of the action of the drug, and is often more quickly satisfied in proportion as both answers are occult.[2] What really should interest him is, as clearly as his mental development permits, some idea of the changes in his body, anatomic and functional, their present seriousness, the chances of death, or of complete or partial recovery, with, in the latter case, the probability of temporary or permanent disability, near or remote, in some organs or functions.

Within the last century prognosis has lost some of its relative importance. Unlike etiology, diagnosis, prophylaxis and treatment, it has no special literature, and is only occasionally the subject of addresses or essays. But much of the so-called prognosis of the earlier periods was really diagnosis, as in Hippocrates' vivid description of empyema, and his remarks in regard to other diseases of the respiratory organs. It also seems a mistake to assume that practical prognosis was more accurate at any period than in later ages of equal enlightenment. While we may admit that great masters, like Hippocrates himself, Galen, Sydenham and Boerhaave, were remarkably accurate in their prognostications, there is no reason for thinking that the rank and file, following their rules without having their keenness of observation and precision of reasoning, were more accurate, or as accurate as physicians of a later period when the formal study of prognosis was neglected, but when other means of knowledge were greater than before. We must bear in mind a fundamental difference in methods. The older prognosis was based on the observation of symptoms alone, and consciously or unconsciously took the standpoint of humoral pathology or some equally imperfect theory. One charge against ancient prognosis is not as serious as some have thought, viz., that the prognosis was made without a definite diagnosis. Even now we sometimes have to be satisfied with a very imperfect diagnosis, and yet may make a very good prognosis, at least for the immediate future. But the older prognosis was almost wholly lacking in anatomic, and totally without chemical basis. Realizing how far short of accuracy the diagnosis must have been in many cases, we can understand that prognosis must have failed almost as often. Moreover, in early medicine, most attention was paid to acute diseases, or the acute terminations of chronic diseases, so that the many important chronic diseases that now make so much of medical practice were comparatively neglected.

---

[1] The Book of Prognostics; the genuine works of Hippocrates, Adams' translation, vol. i.

[2] Striking examples of the virtue of mysterious names are conspicuous in the practice of the popular sect of osteopaths. I could give many examples of the license with medical terms among these people, but as the evidence is derived wholly from patients I cite only one that can be vouched for by medical eye-witnesses. A hospital patient with typhoid fever, with the neck pain not infrequently felt in that disease, requested that his osteopathic physician be allowed to treat him. I was not unwilling, especially as the osteopath gave assurances that he would not attempt to treat the typhoid fever. Two internes "assisted" at the treatment. The osteopath, one of the *sang azul* of his class, after feeling the neck, announced that the transverse processes of three cervical vertebræ were displaced on one side. After some manipulation he pronounced the displacement relieved, though I was sorry to see that the pain was not much less than before.

Whatever shortcomings medicine may have—and those who cultivate the subject most thoroughly feel the needs most deeply—it must be admitted that diagnosis is much more certain than ever before. Not only are we able to distinguish more quickly and more accurately many diseases long known, such as some of the acute fevers, malarial disease, tuberculosis, diphtheria and pneumonia; but we have learned the existence and the means of detecting many diseases formerly confused with others. As examples, let me name only a few, such as the diseases originating in the vermiform appendix and the gall bladder, diseases of the pancreas, many diseases of the blood, a large number of diseases of the nervous system and of the ductless glands, and many diseases caused by animal parasites, of which the sleeping sickness is the most striking example at present.

The older prognosis, far from being negligible, is really of fundamental importance. It gives the accumulated experience of ages that, untrammeled by detail, carefully noted broad and elementary features of disease. As gathered together in the aphorisms and prognostics of Hippocrates, and in the numerous commentaries on them—not always improving the original—it furnishes a fund of inestimable value, but like everything else in medical art, this knowledge is less useful when applied mechanically than when worked over in the crucible of personal experience, tested by other methods and transposed into current formulæ.

Older prognosis was possible to collect into fairly circumscribed space, but this is no longer true.[3] In proportion as diagnosis has become subdivided, specialized and enlarged, and as knowledge of morbid processes has become more complex, so prognosis has become more intricate. Older prognosis was based on broad symptomatic lines, qualified in practice, we may be sure, by a consideration of the patient's constitution. The present basis is diagnosis, but of a different kind. It means not merely a recognition of the name of the disease, but a knowledge of the nature of the disease, still incomplete, but rapidly gaining in fullness and accuracy. In many cases we know the causes, and a good deal of the nature of the causes; in many more we know the seats of the disease, and the anatomic, chemical and functional changes that result directly and indirectly. It is by the study of the altered functions that we can make a prognosis and plan useful treatment without knowing the name of the disease. Clinical and anatomic investigations have been aided by experiments and observations on lower animals, without which our knowledge would have been much less certain than it is. Scores of technical methods have been devised for reactions and explorations; natural forces previously unknown, such as the *x*-rays, have quickly been pressed into service. Long and painstaking observations have thrown much light on complications and sequels, their nature and detection. From all these things the prognosis proceeds naturally in most cases, but here again an indispensable part is a just recognition of the patient's constitution. It is probably true that in this connection we unduly neglect some prognostic aids furnished by the patient, such as changes of the physiognomy. But, on the other hand, we have much more accurate methods of ascertaining the constitutional factor than were formerly available. Constitution is still a somewhat vague term, but we can speak of it here as the result of the functions of all the organs. While the method of representing these functions is still inadequate, we can safely assert that we have much more accurate means of determining the condition of the heart, arteries and veins, and the force of the circulation than we had before; we have gone considerably beyond the recognition of the apoplectic habit in foretelling the danger of vascular disease. We can usually estimate fairly well the efficiency of the blood-forming organs; we can determine with reasonable accuracy the capacity for work of the stomach and intestines, as well as a few details of nutrition and metabolism; we are rapidly getting beyond the limitations of Falstaff's water doctor in fixing the anatomic and functional ability of the kidneys, and we are working toward methods of testing the functions of liver, muscles and nerves. When we have all these factors thoroughly investigated it is probable there will be little need of the *vis medicatrix naturæ,* now an essential part of prognosis.

In the conclusion resulting from these things there is no room for a supposititious clairvoyance, an intangible gift of prophecy, a hypothetic intuition that trained intelligence can not equal or industry surpass. We have a positive foreknowledge, a prescience, a prognosis, corresponding in accuracy and usefulness to our diagnosis, and often in advance of our treatment.

In the foregoing I have spoken of the theory. In the practical use of prognosis the first to profit by that function is the physician. With an accurate prognosis, based on exact and thorough examinations, knowledge of the natural course of the disease and of the patient, the physician foresees the course of the malady and is prepared for changes, emergencies and complications. He is thus enabled not only to preserve his imperturbability, so essential in carrying out necessary measures of treatment, but he can also prepare the patient to meet coming events in better physical and mental condition than otherwise, and, what is often of even greater importance, the self-confidence thus shown stimulates the efforts and the compliance of others concerned in the case.

It is not easy to say how much the patient should share this foreknowledge, and how it should be conveyed to him. In many cases the patient does not ask an opinion, and in many others, either because the present disease seems too slight or for other reasons, the physician does not proffer one. Yet it is good mental discipline to work out the prognosis in every case, as a complement to the diagnosis, and in many the results should be stated to the patient. Many things may conspire to make such statements act either favorably or unfavorably on the patient as on the physician.

Physicians, like other people, can often be classified as either optimists or pessimists. Not that these tendencies affect all parts of the individual's activities. One may be a perfect Pangloss in sociologic, political or climatic matters, and yet take a gloomy view of all his patients. (I am not speaking of those who, rarer in the profession than in some of its parasitic growths, habitually exaggerate the danger of their cases, making every angina a diphtheria, every erythema an erysipelas and every bronchitis a threatened pneumonia). Another who is perpetually cast down by the failure of democratic government or the need of a stronger one, the immorality of the rich and the rule of the bosses, may meet every case with hope and cheer.

---

[3] I have not attempted to include prognostic details, but would refer those interested to "Observations on Prognosis," by P. H. Pye Smith, Guy's Hospital Reports, vol. xliv, 1887, as one of the most comprehensive and suggestive articles in modern literature.

But the practice of prognosis should be cultivated as objectively as any other part of medicine. Not only the therapeutic indications suggested by it, but also the human ones, should be carried out without fear or timidity, without unnecessary harshness, but also without the false benevolence that often does more harm than brutal frankness or ignorance. Here, as in other departments of medicine, the welfare of the patient must be the touchstone by which the action proposed should be proved.

No disease should be looked on as insignificant. Nothing seems less becoming than to hear medical men speaking lightly of disease in general, or of any disease in particular. It is no consolation to the mother whose child has died of one of the rare complications of chickenpox to find that many physicians think that too trivial to concern themselves with it. Nor does it increase confidence in the profession to have hysteria and neurasthenia considered imaginary and ridiculous evidences of perversity, while the impatience, not to say lack of scientific interest sometimes shown toward other less well-defined neuroses, undoubtedly has some relation with the crowded ranks of followers of "isms" of all kinds.

In acute diseases the best general rule is still that of Hippocrates (Prognostics; 19, sect. II): "In acute disease it is not quite safe to prognosticate either death or recovery." A case of this kind, however, should not be considered likely to die unless from a complication, or from the effect of a pre-existing disease, though in certain diseases, such as scarlet fever and diphtheria, the danger of a sudden change and of death should be made known in the beginning. Of course, in cholera and plague, and even in cholera infantum, such information is rarely necessary. In some other acute diseases the study of prognosis prepares the physician not to be unduly elated by the remissions that are so reassuring to relatives. The temporary amelioration in meningitis and peritonitis, in which the patient seems almost free from symptoms, may be mentioned. Less disappointing, but still ominous, is the occasional lull in bronchopneumonia. But in the cases I have just mentioned it is rarely advisable to bring the unfavorable probabilities too strongly before the patient. In these we often need the effects of reassurance and of hope. For the latter as we see it in medical practice is not merely the "kind nurse of old age—hope—which," as Pindar says, "more than aught else steers the capricious will of mortal man," in acute cases especially it is distinctly stimulating to physical and mental processes. Sir Dyce Duckworth,[4] speaking from a ripe experience, recently gave an address on "Hopefulness in Medicine," in which he emphasized this fact, and Niemeyer, equally successful in his career, at his medical promotion defended among others the thesis *medicus semper hilaris.* On the other hand, it is a serious error not to point out, after recovery from certain acute diseases, the possibility of sequels, sometimes months or years afterward, and the advantage of examinations at intervals for the purpose of detecting them before they become inveterate. The thorough examination of the urine at intervals after scarlet fever, of the lungs after pleurisy and all bronchitic diseases, of the heart and arteries after many infectious diseases, often has great practical value.

In chronic diseases there are few exceptions to the rule that the patient should be told the nature of his case as fully as possible. At least, in patients who can be made to understand, and who have a possibility of recovery, of definite improvement or of long duration, there are only individual exceptions. Patients with tuberculosis, heart disease, kidney disease, and disease of the alimentary tract can not get the best possible results unless they understand why and how they should do certain things and why they should avoid others. Tact and patience and a knowledge of human nature are essential in this. The statements made should be as simple as possible, as brief as definiteness permits, without pathologic explanations. Better no statement than an unconsidered or an unintelligible one.

In talks of this kind we too often forget how different are the ideas of non-medical persons, even those who have studied physiology in the public schools, from our own, regarding the body, its functions and diseases. I am always interested in seeing how soon medical students lose the lay point of view, just as one forgets an unused foreign language, and how sometimes they never recover it. Yet unless they do, they lack valuable means of giving aid. Darwin has noticed how everyone who studies profoundly a subject often becomes unaware on what points the ignorant require information. Carlyle, as John Beattie Crozier tells us, imagined his stomach as some old teakettle, thickly encrusted with fur, and I have seen an otherwise intelligent man on the point of using strong sulphuric acid for a cough, because he found by experiment that oil of vitriol dissolved sputum more quickly than any other reagent he had tried. Nor is it enough to make the explanation. We must ascertain whether the statements are understood, and, if possible, whether they are accepted. How often, even with an intelligent individual, after we have stated the existence of a small tuberculous focus, and described the results of rational treatment, we find the patient shutting himself in a dark and close room, taking "lung cures," cough syrups and more or less medicated cod-liver oil, and how often, after demonstrating the sufficiency of dietetic treatment in a digestive disease, we find the patient taking bitters, digestive ferments, usually well neutralized by alcohol, antiseptics and other drugs less easy to classify. So time and patience must be devoted to this part of the work, and we should never be discouraged by failure. I am convinced that there is an improvement in the possibility of carrying out rational treatment, notwithstanding the insidious propaganda of useless or dangerous methods in and out of medical journals.

It is much easier to advise in cases that have a strong tendency to recovery than in those that have not, and there is room for difference of opinion and of practice, in the latter, because the conditions vary with patients according to individuality and accidental factors. A number of aspects present themselves for consideration. In the first place, there is often an element of diagnostic or prognostic uncertainty, where the prospects are better than they seem. Sir Dyce Duckworth[5] has formulated universal experience in pointing out the advantages of the "cautious 'if,'" and if the alternative accepted is the hopeful one, much good can be accomplished in many cases. An interesting example is given by Kussmaul in his fascinating "Jugenderinnerungen." Having made a reputation as a zealous dissector, and having won over his confiding peasants to the many advantages of postmortem examinations, he was asked by the father of a girl with advanced tuberculosis of the peritoneum to arrange for an autopsy on the daughter, when she died. Although Kussmaul, too, thought the daughter was lost, he retorted that he could not speak of an autopsy until the patient was dead. Notwithstanding many obstacles, the girl recovered. The tendency to take the less hopeful alternative is still shown in some cases of tuberculous disease in stages not far advanced, though it is not so common, fortunately, as it was not many years ago, to see such patients given over either to a life of dissipation or of abject despair. The prognosis of valvular disease of the heart is also in a much more optimistic vein than it was fifty or even twenty-five years ago. However, in many cases the prognosis needs to be tested by a therapeutic "if" that is not as well recognized as it deserves. The physical conditions may seem hopeless, and yet if the action of the heart can be improved the case may assume a very different aspect. The advantages of trying were well illustrated by a case in which a woman with aortic and mitral insufficiency and moderately severe loss of compensation was given up as beyond treatment by her family physician. Not knowing this, I told the relatives the impossibility of complete recovery, the danger of sudden death or more probably rapid failure at any time, but also the possibility of improvement and a fairly comfortable life for some time, all the more worth trying to realize, because the condition was not complicated by medicinal action, and the other important organs showed no serious alteration. The family physician then wrote me admitting that he had stated improvement was out of the question, and treatment not worth trying, although under subsequent treatment the patient lived two years and nine months.

---

[4] Duckworth, Sir Dyce: Opening of University of Liverpool Medical School. British Medical Journal, Oct. 3, 1903.

[5] Duckworth, Sir Dyce: Address on Medicine, British Medical Journal, 1896, ii, p. 251.

In cases hopeless in a more certain degree than such as I have just mentioned, it too often happens that treatment is abandoned too early in the case. Patients with cancer of the stomach or other inoperable tumors, cirrhosis of the liver, and many other diseases are permitted to drag out their existence without relief. There are several reasons for this. Sometimes families, having been told the truth about such a patient, refuse all further medical aid, even when the conscientious physician who gives the information points out what can still be done.

Many physicians voluntarily discontinue attendance when they realize that the end is inevitable, with the feeling, doubtless, expressed by Sir William Temple. The latter said that "an honest physician is excused for leaving his patient when he finds the disease growing desperate, and can, by his attendance, expect only to receive his fees, without any hopes or appearance of deserving them." This, however, ignores the fact that in such cases the accomplished physician can often do more real good to the patient than in many cases that recover, while the opportunities for obviating despair, alleviating pain and soothing mental anguish, and for exhibiting thoughtfulness, gentleness, persistence and variety of resources, are more valuable to the physician than any fee. Even in acute cases it sometimes happens that the physician is either discharged or withdraws because the indications seem hopeless, and I have known of patients with pneumonia living for one or two days in this way, the family waiting for the end of a life that with greater effort might have been saved. Sir Francis Bacon described this tendency as one of the deficiencies of medicine, "so that Sylla and the triumvirs never proscribed so many men to die as physicians do." For, as he continued, "the office of a physician is not only to restore health, but to mitigate pain, and not only when such mitigation may conduce to recovery, but when it may serve to make a fair and easy passage."

Improvement in methods of treatment have an important relation to prognosis, in that many diseases considered hopeless at one stage of knowledge, may in another offer many chances for recovery or alleviation. In this connection a critical knowledge of current medical literature is necessary, and a realization of the value of medical evidence. Few things can be more disastrous to the physician's mental development—never completed—than constant change of therapeutic method, but there are differences. One need not try every drug proposed for the treatment of typhoid fever or pneumonia, nor every new antipyretic or hypnotic. But the physician who does not inform himself quickly of the value of surgical treatment in various disease as it is developed, in pelvic diseases, brain diseases, diseases of the appendix, biliary tract, stomach and pancreas, comes very near deserving the reputation of an unscrupulous practitioner. In these departments, too, mistakes are made and exaggerations are inevitable concomitants of progress, but the gain is often distinct and unmistakable, and often changes the prognosis from one extreme to the other.

It may seem that I have taken a too purely medical view of the practice of prognosis. Can we always act from the standpoint of simple diagnosis and prognosis, or must we not at times take into consideration the weakness, fears and prejudices of people? In trying to get the best light on this subject I have for many years noticed the opinions of patients and their relatives, as well as of non-medical writers, and it is instructive to learn how those who are not physicians approach the subject. Many physicians have been influenced by the views of Percival, from whose interesting work on Medical Ethics some of the best parts of the old Code of the Association were taken. Percival said:[6]

> A physician should not be forward to make gloomy prognostications, because they savor of empiricism, by magnifying the importance of his services in the treatment or cure of the disease. But he should not fail, on proper occasions, to give to the friends of the patient timely warning of danger, when it really occurs, and even to the patient himself, if absolutely necessary. This office, however, is so peculiarly alarming, when executed by him, that it ought to be declined whenever it can be assigned to any other person of sufficient judgment and delicacy, for the physician should be the hope and comfort to the sick; that by such cordials to the drooping spirit he may smooth the bed of death, revive expiring life and counteract the depressing influence of those maladies which rob the philosopher of fortitude and the Christian of consolation.

In general, this furnishes a useful guide to conduct, but nevertheless requires some examination. Part of it reminds one of the maxim of John Halle, who as far back as 1596 wrote:

With one consent uniformlye
Comfort the wounded man,
But unto some good friend of hys
Express all that you can.

In the first place, the truth is not always so alarming to the patient, painful as it often is to the physician. In fact, it seems to me this is one part of our duties that does not become less trying with increasing experience. To the sick man, whose thoughts have been turned toward the end longer than others suspect, intimation of a fatal end often brings no shock, but rather relief from the ending of a painful uncertainty. According to the rules of the Roman Catholic Church, a timely announcement should always be given, and those who have witnessed the last days of members of this faith can confirm the statement that good often follows, speaking merely from the medical standpoint, and rarely harm, while the same thing is true of many of other faiths or of no faith. Even where we have to give a fatal prognosis there are certain mollifying influences that can be introduced, aside from those that spring from a tender heart. A hope can be expressed based on the fallibility of human knowledge in general and medical knowledge in particular.

---

[6] Medical Ethics; or a Code of Institutes and Precepts, adapted to the professional conduct of physicians and surgeons, with an appendix containing a discourse on hospital duties; also notes and illustrations, by Thomas Percival, M.D., Manchester, 1803, p. 31.

The rule in regard to giving the patient a good prognosis and the relatives a bad one, can often be followed, but is a very fallacious one on the whole. It is often more necessary to keep up the spirits of the relatives, especially those who have to nurse, than those of the patient, so that sometimes the rule can be reversed with advantage. Darwin[7] cites some interesting and instructive examples of this kind, from his father's practice, and Billroth[8] has expressed himself with much feeling in one of his letters. Moreover, the relatives informed, either from a feeling of compassion or otherwise, may not bring the patient to act on the information, and I have known of serious financial loss befalling a family because the relative entrusted with the task of breaking the news to the patient did not do this. Another risk is that the relatives may divulge the fatal prognosis in such a way as to put the physician in the light of a heartless deceiver, and thereby cause the patient to lose all confidence in him. On the whole, in cases where the patient should know the truth the physician is often the best one to state it, and he should see that this is done before it is too late.

Exceptions to the rule of candor may occur in the case of children, in women with no spiritual obligations or business responsibility, or in exceptional cases in men. No general rule can be laid down, but that such exceptions occur can be confirmed probably by every physician. A striking example of this is quoted by Darwin.[9]

Of course, this part of the subject is closely related to the theory of ethics, and many writers on this subject have touched directly on the question of medical veracity with, as one might anticipate, diametric differences of opinion. Some moralists of the strict school of Kant and Fichte insist that any deviation from the absolute truth is wrong in medicine, as they assert that it would be wrong even for the purpose of saving the whole race. Others believe with Paulssen, who says: "There is not a physician in the world who does not give deceptive answers to his patients, who does not excite hopes that he does not share. He does not blame himself, nor do others, for everyone does the same." Johnson, "the stern old moralist," in his remarks on the subject, laid open a serious flaw in his own logic: "You have no business with consequences, you are to tell the truth." But surely the physician's chief interest is with the consequences, and if he thinks the patient can gain only by misrepresentation, it is just as proper for him to use it as it would be to give a medicine that in other cases might be quite improper. But the physician in such a dilemma would do well to bear in mind the next sentence in Johnson's *ipse dixit:* "You are not sure what effect your telling him that he is in danger may have. It may bring his distemper to a crisis, and that may cure him." Jonathan Dymond, as strict as any one in his morality, threw a gleam of stern humor into the discussion: "Persons frequently employ falsehoods to the sick man who can not recover, lest it should discompose his mind. This is called kindness, though an earnest preparation for death may be at stake on their speaking the truth. There is a peculiar inconsistence sometimes exhibited on such occasions. The persons who will not discompose a sick man for his interest in futurity, will discompose him without scruple if he has not made his will."

This part of the discussion might be indefinitely prolonged, but I think we can never get far away from the principle I intimated in the beginning—that in practical prognosis we must individualize, just as we have to in therapeutics, with the patient's welfare ever the object of our activity.

Accidents that follow an unfavorable prognosis occasionally suggest a revision of methods. I have already alluded to the error formerly not uncommon in the treatment of tuberculous patients. More acute results sometimes follow a fatal prognosis, as in two of my patients who resorted to suicide. One was a man with far-advanced carcinoma of the stomach, to whom I recommended palliative treatment and advised against a useless effort at radical treatment. The patient left for his home, but threw himself from a fast train and was killed. In another patient, a man with a large kidney tumor, apparently with many adhesions, my surgical colleague and I advised against an operation. The patient went to another hospital, and apparently received similar advice, for he shot himself through the tumor, and died in a short time. From a broad biologic standpoint it does not, of course, make any difference whether an individual organism dies as either one of these, or as it would if left to its fate. But no matter how one may feel on the subject of suicide, I have always thought these men less fortunate than another patient with carcinoma of the stomach, also far advanced. To him, in advising against an operation, I added that if he could find a good surgeon who was willing to operate, he might submit. He underwent the operation at the hands of one of the most distinguished surgeons in the country, and died on the table. In such a case the result is often unfortunate, because it prevents operations on other and more promising cases, but for the man himself, fighting to the last, it seems to me one can have only respect.

---

[7] The Life and Letters of Charles Darwin, edited by his son, Francis Darwin, New York, 1887, vol. i. "Called in to see a patient who had been given up to die by the family physician, Dr. Darwin took a different view of the matter and maintained that the man would recover. He was found quite wrong in all respects, and owned his error. He was convinced that he should never again be consulted by this family, and was much surprised at being called in after a few months by the widow. He asked a friend of the widow to find out why he was again consulted. The widow answered that she would never again see the odious old doctor who said from the first that her husband would die, while Dr. Darwin always maintained he would recover. In another case Dr. Darwin told a lady that her sick husband would certainly die. Some months afterward he saw the widow, who was a very sensible woman, and she said, 'You are a very young man, and allow me to advise you always to give, as long as you possibly can, hope to any near relative nursing a patient. You made me despair, and from that moment I lost strength.' 'My father,' continued Darwin, 'said that he had often since seen the paramount importance for the sake of the patient of keeping up the hope, and with it the strength, of the nurse in charge.'"

[8] Briefe von Theodor Billroth, 1902: Speaking of the slow decline of Professor Breisky, and of the attending physician telling the whole truth to the wife, he remarked: "I admit that under certain circumstances this is necessary; but here I do not think it is necessary. How can the poor wife, without a glimmer of hope, bear the weeks until the liberator of all sorrows gently approaches the husband. We should give her courage, and the poor patient morphine. A hard task. But let us remember that every family physician is in this situation hundreds of times, and often has to see his incurable patients daily. If the young man suspected these mental tortures when he enthusiastically enters the temple of Æsculapius he would surely often turn back. To face the unveiled figure of Sais requires all the undaunted resignation that we slowly win in our profession."

[9] *Op. Cit.* "He was sent for by Mr. P., who said 'From all that I have seen and heard of you I believe that you are the sort of man who will speak the truth, and if I ask you will tell me when I am dying. Now I much desire that you should attend me, if you will promise, whatever I may say, always to declare that I am not going to die.'"

This brings up a question on which a few words may be proper—the question of euthanasia. Every few months some one—usually not a physician—proposes that people with incurable diseases should be killed by some painless method. The plan offers so many opportunities for crime that it would be difficult to carry out, but aside from that it involves important principles. The difficulty of telling when the proper time had come would often be insuperable. Aside from examples of fortitude and other virtues exhibited by the dying, how much the world would have lost if a chronic invalid like Stevenson had the cord of his life snapped at one of the times when the *aes triplex* of his soul seemed battered through! To take a less selfish view, we can think of the "pictures of human patience, the visions of ripened character, which have been revelations and inspirations to generations of mankind" (Phillips Brooks), and see these repeated daily in sick rooms of all degrees, while the self-sacrifice and kindness developed in others at such times can not but be of untold benefit to the race. To most physicians the suggestion of any planned shortening of life must be abhorrent. For countless generations they have been doing their utmost to lengthen life and lessen disease. They have shown how to prevent the plagues that formerly made life almost as bad as a perpetual illness for the survivors, and they have also shown how many deaths can still be prevented. On the other hand, they can, in most cases, so treat the dying man that the bitter anguish often associated with death is absent, that life is not only less painful, but actually longer, so that they will continue to follow the rule of the Father of Medicine, and "give no deadly medicine to any one, even if asked, nor suggest any such counsel."

THE ASSOCIATION OF SURGICAL LESIONS IN THE UPPER ABDOMEN.

ORATION ON SURGERY AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT ATLANTIC CITY, JUNE 7 TO 10, 1904.

WILLIAM J. MAYO, A.M., M.D.
Surgeon to St. Mary's Hospital.
ROCHESTER, MINN.

The history of medical advance from the empirical treatment of symptoms to scientific expectancy, has been based on the study of death and modern research work. The spirit has been fine, although somewhat pessimistic. The great advances have been along the line of preventive medicine and in the elucidation of problems connected with the etiology of disease.

Surgical progress has been, to a certain extent, through similar channels; the spirit, however, has been one of magnificent optimism. The great advances in surgery have come from the clinical side, modern technic having enabled examination of primary conditions during life.

As a groundwork for the study of medicine the pathologic laboratory and autopsy room offer unrivaled advantage, but they teach end results only. Who of us has not admired the precision with which a trained observer makes a diagnosis? A few days later one visits the autopsy room and here observes that this almost clairvoyant analysis was correct. At the same time, we must also acknowledge that the patient has not profited; it means a hundred pages of pathology and two meager lines of treatment. How many times do we notice in the autopsy revelations that the original lesion has been but slight, and at one stage easily curable, the pathology present largely the result of secondary complications and terminal infections?

The postmortem has been an institution for years, yet what did we know about appendicitis until surgery led the way, or about gallstone disease, supposed to be an "innocent postmortem finding," until operation opened up the field? Did knowledge of extrauterine gestation come from the autopsy? By no means. It was through the surgeon's knife, and why? Because secondary conditions so often mask the original lesion at the postmortem. On the contrary, our understanding of acute conditions causing sudden death has been brought about by dead-house investigations; for instance, fatal hemorrhage and perforation placed acute gastric ulcer on a sound foundation. Not so chronic gastric and duodenal ulcers with late death from complications, cholangitis from gallstone disease, and chronic pancreatitis from the same cause. These conditions could not be correctly studied, excepting after death from accidental cause, and real progress lay dormant until surgery invaded the field.

From research work we have profited much; we are gaining rapidly by this means day by day, but we can not compare the animal to the man, nor can we always artificially create similar conditions. Like the postmortem, it has its limitations, yet these two fundamental methods have enabled us to advance. Without them we would still be in the middle ages. Now the time has arrived, in the light of these investigations, to view conditions from a new standpoint at a time when the lesion is in its infancy, long before the postmortem, while the patient may be benefited and the research work applied to the elucidation of living problems.

The medical man must haunt the operating theater as he has haunted the autopsy room and the laboratory. The times have changed; we must have more treatment and less pathology. It is here that surgery wins its triumphs. We must not forget, however, that to physicians of pathologic training we owe the knowledge which enables us to approach the subject. Courvoisier was the real father of gallstone surgery. It was Balzer, Fitz, Opie and others who cleared up the pathology of pancreatitis, and surgery followed their lead. It is in the union of the internist and surgeon that progress is most rapidly made, and in the readjustment of science the former will be the architect and the latter the master builder.

Once more the physician and surgeon will come together, and the mistakes of endeavor in new fields will receive timely correction at the hands of the pathologist and experimental worker.

The surgical borderland of to-day lies in the upper region of the abdomen, a locality until recently considered almost purely medical. What are the reasons for this invasion, and have the results justified the attempt?

Surgery must be judged on three grounds: First, the mortality of the operation itself and the question whether this is greater than under the expectant plan; second, the permanence of cure contrasted with medical treatment; third, the question of disability, either introduced by the operation itself or the natural length of time which the healing process involves. On each one of these considerations we must answer yes, and we can go still farther and say that earlier operation would reduce the mortality and increase the permanence of cure and lessen the disability.

Certain parts of the body are so closely related in their anatomy, function and pathology as to be almost necessarily considered as part of the same system. The generative organs of women form so distinct a field of work as to have built up a specialty. Can we separate diseases of the kidney from the ureter, bladder and urethra? By no means. Each may stand in an etiologic relationship to the others which can not be ignored.

In the upper abdomen we have attempted to study the stomach independent of the associated organs, the liver and bile passages, the duodenum and pancreas. The result has been a confusion in diagnosis and treatment. The palm of a hand may cover a serious lesion of any one of these organs, and that, too, at the point of greatest liability; not only so, but any one of this group may start a pathologic process which may extend to any one of the others, and with fully as great frequency as occurs under similar conditions in either the generative or urinary systems.

Note the disturbance of the stomach which occurs with gallstone disease; the adhesions to the duodenum and the pancreatitis, an association direct as it is vital. Again, let me call attention to chronic ulcer of the stomach with adhesions to the pancreas, secondary ulcer of the duodenum adherent to the bile passages or gall bladder. These are not fanciful pictures, but drawn from every-day work. I have no hesitation in saying that with an operative experience of over 1,400 cases of this description, mistakes in exact diagnosis are still common, and in many instances unavoidable. The history may be the only valuable diagnostic resource when the patient comes to us, and we all know how unreliable that may be. Given a history of painful attacks which have been very severe, but which have completely ceased, with tenderness on deep palpation in the epigastrium, and we may have disease of any one of these four organs, and not infrequently an association either direct or indirect of the pathologic process. If we clearly understand the possibilities of error, we are better prepared to meet complications or execute a change of front and operate on one organ when another procedure was planned. In the majority of cases a pathologic diagnosis is possible, and one can say with certainty, "This is gallstone disease," or "This is ulcer of the stomach"; but in a considerable minority a surgical diagnosis is the best that can be made. That is, we can say: "In this locality is a diseased process which requires operative treatment, the exact nature of which must be determined by incision." The patient does not come to us for the purpose of having a certain operation performed, but seeks relief from suffering and disability.

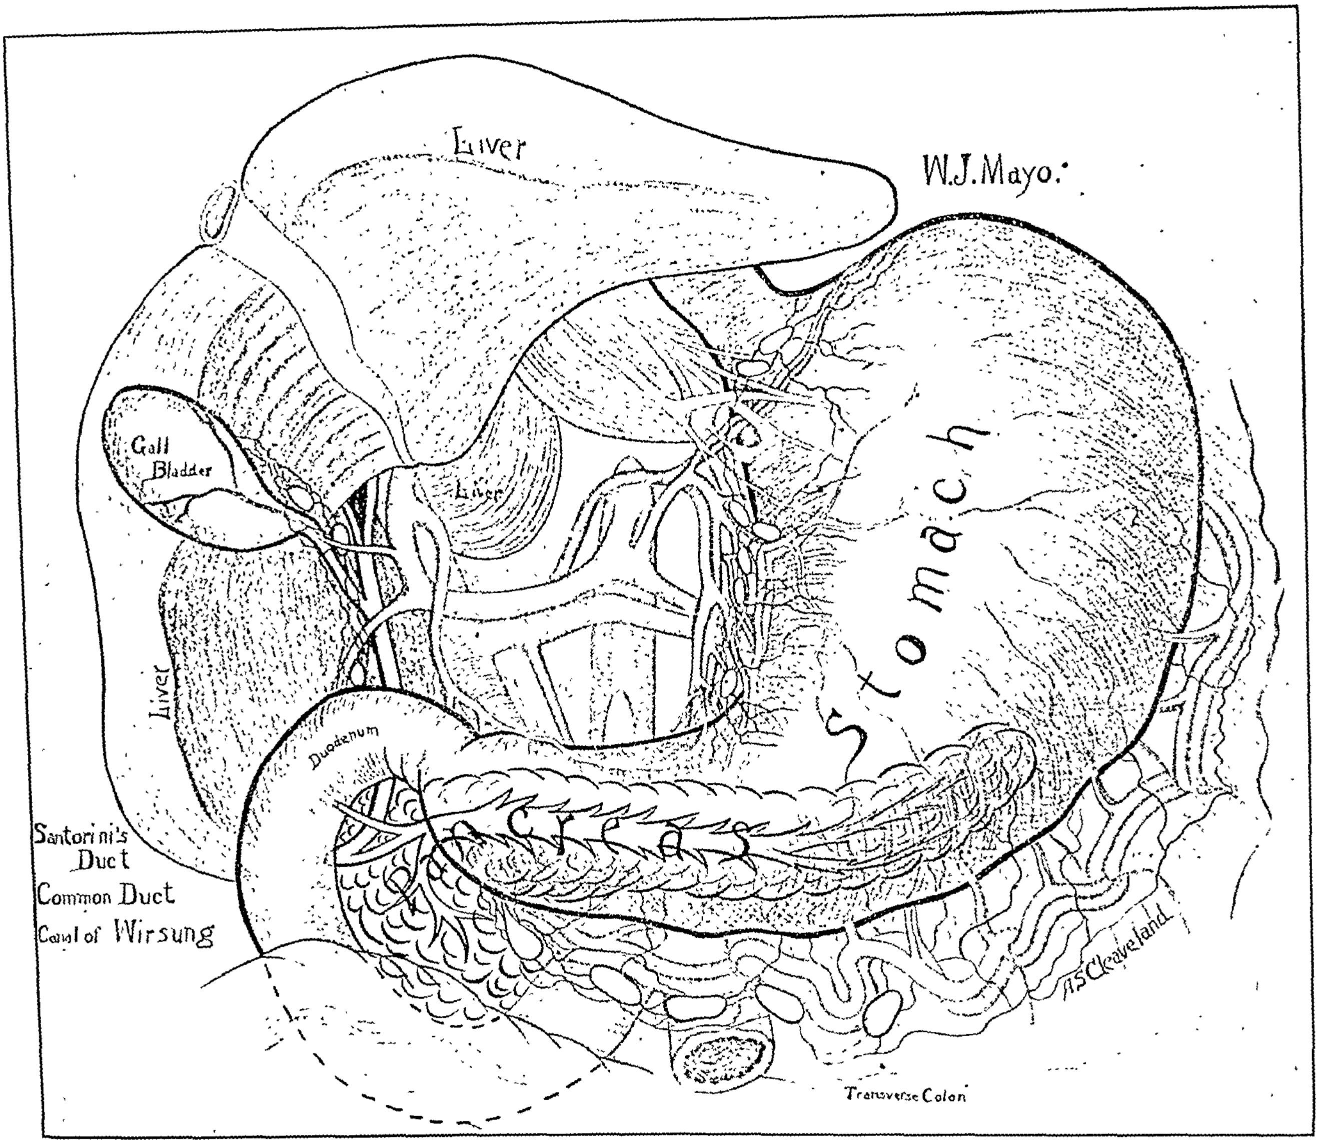
Let me call your attention for a few minutes to the anatomic diagram, showing the nearly vertical position of the stomach with the pylorus in the middle line of the body, and but little elevated above the lowest point of the gastric cavity. It is turned upward and to the right just enough to prevent the weight of the gastric contents bearing directly on the sphincter apparatus. The only portion of the duodenum in which we are interested is the four inches lying between the pylorus and the papilla of the common duct of the liver and pancreas. This may be called the vestibule of the small intestines. Its position subjects it internally to the perils of ulcer from the acid gastric juices which its thin tunics but inadequately resist. Externally its function is often interfered with by adhesions to the gall bladder and bile tract, secondary to gallstone disease. This unoffending bit of intestine is so often offended against as to cause it to become the most frequently diseased portion of bowel of the same length. The remaining eight inches of the duodenum is protected by the alkaline secretions of the pancreas and liver. Its fixed position and peculiar horseshoe shape, with its delivery point nearly as high as its origin, enable it to mechanically slow the ingested material during the mixing process for which its large caliber affords accommodation.

The anatomy of the bile tract is equally interesting, and especially the relations of the common liver duct to the pancreatic duct and the duodenum. There is continuity of mucous surface, each protecting itself from the secretions of the others by the mechanical washing effects of its own secretion, the joint discharge and a feeble sphincter apparatus preventing entrance of the duodenal contents.

The gall bladder, as it furnished the initial lesion in more than one-half of the diseases of this group, is of great interest. Like the appendix, an obsolete organ of storage function and limited outlet, it gives rise to a variety of troubles, which we are only of late beginning to appreciate. It is an old aphorism that "Nature finds mischief for idle hands to do." The gall bladder has a capacity of about an ounce, and as we find almost universally in organs of storage function, the neck is raised slightly above the lowest point to prevent the weight of contents resting directly against the outlet. The little pouch thus formed may be called the pelvis of the gall bladder (Brewer). It is here that the obstructing stone is so frequently lodged in cystic impactions. Murphy observes that the fundus of all organs has but few lymphatics, while the region of the neck has an abundant supply; hence, even with septic contents, there is but a mild reaction when the pelvis is obstructed, as compared with the startling temperature curves of duct stones.

The pancreas, composed of two originally separated parts. has in nearly half of the specimens which have been examined two patent ducts, that of Wirsung, which is the important one, uniting with the common liver duct. The minor duct of Santorini, however, has a possibility of useful function in certain diseased processes, as pointed out by Opie. The pancreas was originally an intraperitoneal organ, becoming retroperitoneal by a later evolution (Huntington), and in this anatomic peculiarity Brewer believes lies one of the reasons for the diffusion of fat necrosis resulting from acute pancreatitis. Mikulicz has called attention to the fact that adhesions to the pancreas in gastric cancer gave a mortality of 73 per cent. in his resection cases. Robson also notes the pancreatic mischief occasioned by perforating gastric ulcer on the posterior wall.

The blood supply of this group of organs is almost entirely from a single source in the celiac axis. It has been experimentally developed that the severance of all connections of the pancreas excepting its blood supply, does not check secretion if food is placed in the gastrointestinal tract. In the nerve supply from the pneumogastrics and sympathetic ganglion, we find the same direct relationship involved. If we study the function we see the same association. The stomach can be compared to a mill, the fundus the hopper, in which the food is macerated in a weak solution of pepsin and hydrochloric acid, and the muscular pyloric portion the grindstones in which the masses are broken up into a homogeneous whole. The entrance of food into the duodenum causes the outflow of biliary and pancreatic secretions, the absorption returning to the liver by way of the portal vein. This is so elementary that you wonder that I should refer to it, yet the causation of the common surgical lesions lies in perversion of these fundamental functions, and is just as simple. Mechanical injury of the pyloric portion and excessive acidity of the gastric secretions, under anemic conditions, give rise to ulcer and lie behind the precancerous lesions which Ochsner notes is found in the history of cancer of the stomach in the majority of cases. The acidity of the gastric secretions renders the contents of the stomach, when turned into the intestine, relatively sterile, but increases the liability of ulcer of the duodenum. The sterility of the upper intestinal tract is still further increased by intestinal absorption, as shown by Adami, the bacteria being picked up and destroyed in part by the glands. Many germs are, however, carried to the liver, and here either annihilated or screened out of the blood in the portal vein and discharged with the bile. We must look on the bile as always containing a few bacteria, and it is probably this attenuated infection of bile retained in the gall bladder which gives rise to gallstone disease, which in turn is the chief factor in the production of duct inflammation of both the liver and pancreas.



These considerations, so briefly outlined, taken in conjunction with the embryologic origin, justify the grouping of *the surgical lesions of the upper digestive tract,* and at once enable the diagnostician to associate the symptoms and the surgeon to direct his attention, not to one, but to the entire group of organs. The burden of proof lies with the practitioner, not only to demonstrate that the disease rests in one organ, but to differentiate and show that no other is involved.

The art of the diagnostician lies in the proper valuation of the signs and symptoms of disease in organs of associated function and pathology. The instinct which seems to lead some men to a correct conclusion, and by a mental process they could not themselves analyze, usually depends on few things, the immaterial or in-conclusive evidence being unconsciously discarded. For instance, note the value of the colic in the diagnosis of gallstones. The typical attack comes on and stops abruptly, is relieved by vomiting or a feeling of movement of gas, is irregular in time, in regard to food, and not accompanied by temperature or pulse elevation, and leaves the patient able to attend her duties almost immediately after cessation of pain. While the pain lasts, it is excruciating, felt in its greatest intensity in the epigastrium, radiating upward behind the sternum and into the back. The distress penetrates to the right side, but occasionally to the left, and lasts from a few minutes to six or eight hours. When the patient comes to the physician it may have been years since the typical attacks; he may have forgotten them, the present trouble complained of being pain, digestive disturbance, and tenderness on deep pressure over the gall-bladder region. The history of the early attack is worth more than the physical examination in many cases. Compare it with the pain in gastric or duodenal ulcer, which may be just as severe, but lasts a day or two longer, especially when due to regional peritonitis, and is accompanied by gastric symptoms and local tenderness. The patient diets, which means he reduces his food supply. The symptoms last more or less for some days or weeks, and the interval of apparent cure gives some weeks or months of comparative health.

Acute perforations of the organs of this group are relatively common and give rise to symptoms which would be at once recognized if they occurred in the region of the appendix, but occurring in the upper abdomen too often go to a fatal issue unoperated. The initial symptoms are remarkably alike, whether of the gall bladder, the duodenum, stomach or acute perforation of the pancreas with fat necrosis. The onset is essentially the same in each. Sudden extreme epigastric pain, with collapse, ushers in the attack, and muscular rigidity, as a rule, comes on early. The diagnosis of perforation, if we are on our guard, is easy, although it may be difficult to say which organ is affected; but this does not make any difference. The vital consideration is that it has happened, and immediate operation must be performed.

In 811 operations on the gall bladder and bile tract we had 4 acute perforations of the gall bladder, with but one recovery, although the average mortality in the benign series was but 4.47 per cent. In 45 operations for duodenal ulcer, 4 acute perforations occurred, with 2 recoveries, while in the 41 operations for subacute and chronic ulcer there was only one death. In 469 operations on the stomach, 5 perforations occurred, with 2 deaths. In 32 operations for diseases of the pancreas, there was only one operation for acute pancreatitis and fat necrosis, with recovery. This gives 14 cases of acute perforation, with a mortality of 50 per cent., and why? Because the operation was usually too late. The death rate in over 1,150 operations for subacute and chronic benign conditions of this group of organs averaged a little less than 5 per cent., counting as a death from operation any patient dying in the hospital without regard to cause or time elapsed between the operation and the fatal issue. If we add to this mortality of 50 per cent. in operations for acute perforation, the cases seen in a moribund condition beyond even attempt at relief, and the still larger number in which death occurs without an ante-mortem diagnosis, we get some idea of the appalling nature of the disaster. To be successful, operation must be immediate; the condition is as imperative as hemorrhage from an artery of the third class. Few recover operated on later than ten hours after perforation. The conditions simulating perforation in the upper abdomen, such as thrombosis of the mesenteric or splenic vessels, diaphragmatic and duodenal hernia with strangulation, and so forth, are rare, and likewise call for early operation.

As a rule, the history and location of the early acute pain will furnish evidence as to the origin of the trouble. Preceding perforation of the gall bladder there are often symptoms of several days' duration with a history of gallstones. The acute pain occurs in the gall-bladder region. Early drainage with removal of the gall bladder should give a mortality of not to exceed 10 per cent.

Duodenal perforation usually occurs in cases of chronic ulcer with years of symptoms preceding; but the immediate onset is exceedingly acute, and not ushered in by a few days or hours of prodromata, as is often the case with the gall bladder. The location of the early pain is just to the right of the median line. The liquids gravitate at once to the appendiceal region and simulate perforated appendix. The rapid diffusion of escaping contents is fatal to delay. Operation for acute perforation of the duodenum is rarely successful after eight hours. Suture of the perforation with suprapubic pelvic drainage, and after-treatment in the sitting posture (exaggerated Fowler's) in early cases should give 80 per cent. or more of recoveries.

Gastric perforations occur on the anterior wall, according to Brunner, 7 times to 1 posterior, and near the cardiac end 5 times to 3 times in the pyloric portion, and near the lesser curvature 122 times to 16 times near the greater curvature. The initial pain is usually to the left of the median line, and early diffusion of fluids is to be expected. Only 10 per cent. occur without previous symptoms of chronic ulcer. The results of operation being in direct ratio to the amount of gastric contents, and the length of time which has elapsed, the treatment is similar to the duodenal ulcer.

The term perforation of the pancreas from inflammation with resulting fat necrosis is a purely pictorial expression, and not a pathologic entity in the sense the word is used in the preceding remarks, yet it conveys the idea and calls attention to the value of peritoneal drainage in its treatment, as shown by Woolsey. The symptoms are sudden pain in the epigastrium, collapse and early extreme distension of the abdomen. On opening the peritoneal cavity, free fluid often of a hemorrhagic character is evacuated. The little fatty masses in every direction and the enlarged pancreas call attention to the source of the trouble. This particular phase of acute pancreatitis can not be separated from the hemorrhagic type in which treatment is as yet in an unsettled state. Those interested in this question will find a mine of information in the Hunterian lectures for 1904 by Mayo Robson.

The group of acute perforations gives an unsatisfactory mortality, with a prolonged period of disability from drainage, and without a certainty of permanent cure of previous underlying conditions. This will not long continue. Like acute gangrenous appendicitis, the condition will be recognized early with corresponding improvement in results.

The diagnosis of the chronic infective lesions of the organs of this group is in a far more satisfactory condition. The general mortality of gallstone operations is not above 5 per cent., taking the cases as they come, but even this is too high. Grouping the cases in which the entire process is limited to the gall bladder, the mortality is from 1 to 2 per cent., and depends to a large extent on the general condition of the patient. Secondary complications, chiefly those which involve the hepatic and common ducts with resultant cholangitis, pancreatitis, and so forth, are responsible for the death rate. As practically all of the patients have symptoms on which a diagnosis could be based previous to the complications, it will not be long before early operation in patients otherwise in good health will be the rule as it is now in chronic and relapsing appendicitis. Not only is the mortality thereby reduced, but the disability is likewise lessened. The average stay in the hospital for uncomplicated gallstone patients is slightly less than seventeen days; the convalescence of the complicated duct cases is prolonged one or two weeks.

Chronic infections of the pancreas are usually secondary to gallstone disease, and, as a rule, do not occur excepting where the common duct has been directly irritated by the presence of calculi, although the consequences may continue for some time after the passage of the offending body. The results of drainage of the gall bladder and bile ducts are extremely satisfactory. In our series of 32 cases there were but 2 deaths; these patients had coincident suppurative cholangitis.

Chronic infective lesions of the stomach with ulcer as a type are becoming better understood every day, as surgical operation discloses the actual conditions present. The primary mortality of operations for their relief are in a fairly satisfactory condition, but as to ultimate results we can not say definitely. For the obstructive complications the result of ulcer, there can be no question as to the relief afforded and at a nominal risk. The dilated stomach with retention or stagnation of food suggests at once drainage operations with gastrojejunostomy as the type. We have patients of this description alive and well more than twelve years after operation.

Chronic ulcer without mechanical obstruction gives a less promising outlook. The very fact that there is normal gastric motility indicates that gastroenterostomy or other drainage operation is less necessary. Our results in operations for this description of lesion have not been wholly satisfactory, and furnish a considerable percentage of secondary operations and failures to relieve.

Cannon's experiments have shown the same results. A gastroenterostomy on a normal stomach of an animal does not drain the gastric cavity, even if placed at the lowest point. The gravity advantage of the gastroenterostomy is overcome by intra-abdominal tension, and the food, by muscular action, is carried out the pylorus rather than the artificial opening. The magnificent showing of gastroenterostomy in obstruction has led to the indiscriminate performance of the operation in those cases of ulcer in which gastric drainage is normal. This particular phase of the subject must be further investigated.

Chronic ulcer of the duodenum is relatively more common in the upper two inches than in any corresponding portion of the stomach. It is especially liable to perforate, although its sheltered situation usually leads to adhesive protection. Many pyloric ulcers will be found to have their origin on the duodenal side. Gastroenterostomy is the operation of choice as it diverts the irritating gastric juices and food products from the sensitive surface, thus promoting rapid healing. We have performed gastrojejunostomy 286 times for all purposes, with a mortality of 5½ per cent. in the benign series. The recent improvements in the technic of gastroenterostomy have greatly reduced the mortality and largely eliminated the causes of failure to mechanically relieve the conditions. Moynihan well says that "the surgeon may not unreasonably expect that from being a last resource gastroenterostomy may be considered as a method of treatment worthy of consideration in a much earlier stage of chronic ulcer of the stomach." Excision of gastric and duodenal ulcers would seem to be a wise procedure, but is open to certain strong objections. In 20 per cent. of cases more than one ulcer is present, and one or more may be undetected or lie in an inaccessible situation. It leaves the ulcer tendency unrelieved, and more ulcers may form. Rodman has suggested the removal of the pyloric or ulcer-bearing portion of the stomach with complete closure of both duodenal and stomach ends and independent gastrojejunostomy. We have followed this plan in 5 cases of inveterate ulcer relapsing after gastroenterostomy, with good results. The gastroduodenostomy of Finney is a most excellent operation, and we would predict a wider field of usefulness than it has enjoyed. We have performed this operation 46 times, with one death, and no relapse. The theoretical objection is that in open ulcer the food must pass the ulcerated area before reaching the widened pylorus, and obstruction has no part in the production of ulcer, as is shown by the development of duodenal ulcers. Pyloroplasty must be discarded. While we had no death in 20 operations, we had 7 relapses.

In briefly calling attention to the malignant diseases of this group of organs, the writer would emphasize the possibilities of cure by means of operation. In the gall bladder we found 4 per cent. of cases at the operating table had malignant disease, and all of these cases had gallstones present or evidence that they had been present at one time.

Since it has become the practice to remove all thick-walled gall bladders as useless and a possible source of future trouble, many cases of malignant disease in an early stage have been in this way, as one might say, accidentally cured. We have met with several such instances.

Cancer of the stomach is the most common type of malignant disease in the human body, constituting one-fourth to one-third of the total number. The radical treatment of gastric carcinoma is now on assured ground, with a mortality of 10 per cent., or less in favorable cases, to 20 per cent. in late but still operable disease. The only necessary thing for success is an early diagnosis, and this must be on clinical grounds, supplemented by early exploratory incision. In 46 gastric resections for pyloric cancer we had 7 deaths.

The profession may well look on the surgical achievements in this new field of work with pardonable pride. That there are many shortcomings must be admitted, but in the history of surgery there has never been a territory opened up with equal rapidity, nor one in which the physician and surgeon have worked together in such harmony for the common good. The statistics on which this paper is based represent the operative experience of Dr. Charles H. Mayo and myself.

Our State Medical Societies.—When the importance of these organizations is considered with the good work they are doing we fail to understand, remarks the *Medical Recorder*, how any legal practitioner of medicine can be contented until he has affiliated with his local society. All prejudice should be laid aside and each one should find that his fealty rightfully belongs to his state organization. Don't disqualify yourself by failure to join your local society. Be up and doing.

PREVENTIVE MEDICINE: ITS ACHIEVEMENTS, SCOPE AND POSSIBILITIES.

ORATION ON STATE MEDICINE AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT ATLANTIC CITY, JUNE 7-10, 1904.

HERMANN M. BIGGS, M.D.
General Medical Officer New York City Department of Health; Professor of Therapeutics and Clinical Medicine and Adjunct Professor of Medicine, University and Bellevue Hospital Medical College.
NEW YORK CITY.

The terms sanitary science, public or state medicine, and preventive medicine, have frequently been used as almost synonymous. The latter term, "preventive medicine," however, has sometimes been restricted in its application to the prevention of the infectious diseases. In the broad sense, preventive medicine comprises both general prophylaxis and individual prophylaxis, and applies to all forms of disease, not simply to the infectious diseases. Preventive medicine is an applied science, which deals with the preservation of the health both of the individual and of the community.

No subject more vitally concerns the welfare of a community than that pertaining to its healthfulness. How the inhabitants live and how and at what age they die, what is the extent and character of the morbidity occurring among them and what are its causes, are questions of momentous importance. They are essential features in the problem, whose solution will teach men how they may live longer, healthier, and therefore happier lives.

In rural districts the average healthfulness of the inhabitants depends largely on natural conditions, such as elevation, climate, soil, and, to a much less extent, on the artificial conditions produced by the handwork of man. In densely populated cities, on the contrary, the natural conditions become relatively unimportant features in determining the degree of healthfulness, so much do they become subordinated in many cases to the artificial conditions which have resulted from the lives, labor and occupations of the inhabitants. It may be said with certain limitations that the inhabitants of any city in the temperate zone now have it largely within their power to determine what degree of healthfulness their city shall have. A high morbidity and a high mortality in any urban population depend largely on some remediable features of an unsanitary character, such as the sewerage of the city, the occupations, habitations, food and water supplies, and the habits of the inhabitants—all factors which lie to a great extent within their control. Hence, when any city in modern times has a high annual death rate, for example, 30-35 per 1,000, as was formerly the case in New York, Liverpool and other cities, instead of a death rate of 17-18 or 19 per 1,000, as now exists in London, Berlin and New York, it is because conditions are permitted to exist partly from the neglect, indifference and ignorance of the people, and partly from the lack of proper facilities and necessary efficiency on the part of the authorities.

The achievements of scientific medicine have now placed at the disposal of the sanitary authorities such full knowledge as to the causation of so large a proportion of the diseases producing death, and of the means by which they may be restricted or prevented, that the determination of the average death rate is in their hands. This statement is not, of course, intended to mean that it is now possible to prevent or stamp out local epidemics of influenza, pneumonia, cerebrospinal meningitis and some other infectious diseases, but it is intended to cover the average general death rate of a city for a series of years.

The expectation of life at birth in certain manufacturing cities of England has been but little more than one-half that of the healthiest districts of England. Until recent years it was 25 or 26 years in Liverpool and Manchester, 37 years in London and 46 years in Surrey, a healthy country district. Even at the age of 30, the expectation of life was seven years more for England as a whole than it was for the inhabitants of Manchester. I have estimated that the expectation of life at birth in New York City in 1866 was only a little more than 25 years, while in 1903, calculated on the death rate for that year, it had almost doubled, and equaled about 42 years. For the 7-year period ending in 1873 the death rate under 5 years in New York City was 123 per 1,000 of the population at these ages. For the year 1903 the death rate under 5 years was 56. On the present estimated population at these ages, this reduction equals a saving of more than 28,000 lives annually.

These considerations suggest the vast importance of the healthfulness of the community to the individual at every age, and to the community as a whole, for on this depends not only the relative freedom from illness, but also the probable lifetime of each member.

In the casual consideration of the healthfulness of communities as compared with the conditions existing in earlier times, we are inclined to think without investigation that there has been but little advance in modern times and that while some diseases have been greatly restricted or entirely stamped out, these have been replaced by others equally as fatal to the human race. A little study, however, shows how erroneous are these views. In the seventeenth and eighteenth centuries the average annual death rate throughout the civilized world was at least 50 per 1,000 of the population, and probably it was much more than this. From 1628 to 1635 in London, these years being free from pestilence, the average death rate was 50 per 1,000, and the absolute annual mortality for 24 years, from 1620 to 1643, was over 70 per 1,000.

The death rate during 1902 in London was only 17 and a fraction per 1,000. The mean expectation of life in London for the decennial period, 1771-1780, as calculated by Price's table, was 19.6 years, the annual mortality being 51 or 52 per 1,000; while from 1831 to 1835, although an epidemic year is included, the death rate had decreased to about 32 per 1,000. In 1894 the mean expectation of life at birth for all England had more than doubled that of 1780 in London, so that it was nearly 41 years, and for London alone it was 37 years. From 1771 to 1780 in London not less than five in each thousand of the population died annually of smallpox; in 1810 this mortality had sunk to 2 per 1,000, and in 1835 to 0.8, and in recent years it has been an absolutely insignificant decimal. Fever as a cause of death declined in almost the same ratio, from 6.21 in the decennial period ending in 1780 to 2.64 in 1810, and 1.14 in 1835. In the sixteenth century fever, plague, cholera and dysentery destroyed annually 31 out of every thousand of the population of London, or nearly twice the total deaths occurring now from all causes. These diseases at the present time, as causes of death, do not equal in London 2 per 1,000 annually of the population.

According to the English life tables up to 1875, 518 out of every thousand children in Liverpool died during the first five years of life; 351 died in London and 205 in the healthy rural districts of England, while in the whole of England 297 out of every thousand died during this period of life. In old New York City (comprising the boroughs of Manhattan and the Bronx), for the seven-year period ending in 1873, 616 out of every thousand children born died during the first five years of life. As computed by the death rate under 5 in 1903, 280 would have died during these same five years. This mortality, while still far too high, equals a reduction of nearly 60 per cent., and as calculated for the estimated population at these ages, means a saving of about 20,000 lives a year in these boroughs. The death rate in the period over 5 years of age has naturally shown a much smaller decrease, although it has fallen from 19 or 20, as it was in 1865 and '66, at the time of the organization of the Department of Health of New York City as at present constituted, to about 14 for the year 1903, being a reduction of nearly one-third. This has been accomplished notwithstanding the fact that the old city has increased during this time from a population of about 750,000 to more than 2,200,000.

It does not seem necessary or desirable for our present purpose to consider in detail the causes of this decrease or the special diseases in which it has taken place, but the facts suffice to indicate the great achievements of preventive medicine during the past four decades. Expressed in human lives, it means, in the boroughs of Manhattan and the Bronx, a saving of over 30,000 lives a year, and, computed at the same rate for the whole city, a saving annually of more than 50,000 lives. I would not be taken as intimating that all of this has been accomplished through the agencies which we usually include under the head of preventive medicine, or that it has been the result solely of the action of the sanitary authorities. Such an interpretation would be very far from the truth, for many agencies have been at work in the production of these results. But preventive medicine, as I conceive its purposes and scope, should include all of those agencies which are essential and direct factors in the prevention of disease and the preservation of life. These agencies are not necessarily all under the direct control of the sanitary authorities.

In these introductory remarks, and in much that follows, I have taken many illustrations from conditions which exist in New York, because I have been familiar with the sanitary affairs there for many years, and the illustrations which it furnishes serve our purpose as well as if selected from many different states or communities.

It has long seemed to me that the work of the sanitary authorities in this country was too much restricted and the general conception of the scope of their functions was narrow and out of harmony with the spirit and development of modern scientific medicine.

Sanitary work has been pretty well limited along certain old and well-defined lines, much to the detriment of the public health. The medical profession has unconsciously contributed no small part to this condition, because of the existence too often of a certain antagonistic attitude toward the action of the sanitary authorities and the feeling that the occupation of a larger field by them would be detrimental to the best interests of the medical profession. The latter has too often resented and opposed any movement to enlarge the field of preventive work, and has often insisted that its operations should be kept within the traditional narrow lines. Until in very recent years the operations of the health officers have been chiefly confined to the measures adopted for the prevention of the more readily communicable diseases, commonly called contagious. These usually included smallpox, diphtheria and scarlet fever, and at intervals, yellow fever, cholera, epidemic dysentery and typhus fever. More recently typhoid fever and measles, and indirectly the diarrheal diseases of infants, have been generally added to this list. But even in regard to the diseases referred to, the measures adopted have been of an elementary and most unsatisfactory character. It must be admitted, however, that until our knowledge of the causation of many of the infectious diseases was rendered more exact by the discoveries in modern bacteriology, sanitary procedures were of necessity largely empirical, and disinfection was either entirely wanting or the methods employed were quite inefficient.

The scope of the sanitary measures in force with reference to the ordinary infectious diseases has in recent years been greatly broadened. More than ten years ago the Board of Health in New York assumed the position that all facilities and procedures looking to the prevention and cure of the infectious diseases should be afforded by the Department of Health. The establishment of the methods for bacteriologic diagnosis and the facilities for the serum treatment had their origin there, and have since been widely followed.

General prophylaxis, or that portion of preventive medicine which should come directly under the supervision of the health authorities, has or should have, a broader scope than that indicated, and should include the supervision, not only of those diseases which have generally come within sanitary surveillance, but also all the infectious diseases which from their nature are to a greater or less extent preventable, in addition to all other forms of disease which are the result of unsanitary living, occupations, habitations or surroundings, including those diseases arising from manufacturing, mining, or other industries which, on account of their nature, are peculiarly or especially injurious to health. It should also include with greatly increased powers and breadth of jurisdiction, the surveillance of the water and food supplies and the sewage disposal.

To return for a moment to the consideration of the infectious diseases to be included in this list, there is a large class of different types of the infectious diseases which are well recognized as being more or less preventable but are not included in the registration returns. These are not dealt with at all by the sanitary authorities, or only to a very limited extent. Mention may be made in this connection not only of tuberculosis in all its forms, whooping cough, mumps, chicken-pox and cerebrospinal meningitis, which have been included in the registration returns by some authorities, but have not, as a rule, been dealt with by them, but also of puerperal fever, erysipelas, pneumonia, the diarrheal diseases of infants, dysentery, malarial fever, influenza, the contagious diseases of the eye, and certain parasitic diseases of the skin, as well as some of the rarer diseases occurring in both animals and man, such as rabies, tetanus, anthrax and glanders.

The inclusion in the registration returns of such a long list of infectious diseases as has been here indicated requires considerable modifications and expansion of the ordinary sanitary procedures, and such action at first thought is likely to arouse opposition and unfavorable criticism from the medical profession. Such opposition and criticism, however, I believe is without proper justification and arises from an erroneous conception of the proper scope and functions of the authorities and their relations to the medical profession and to the people.

There has long existed a belief in the medical profession, and to a considerable extent it has also been a part of the conception of the sanitary authorities of their functions, that the registration of a case of any kind of infectious disease involved some surveillance of such case by the authorities. The slightest consideration would at once show that with relation to many of the diseases mentioned no such surveillance could be of any real service, and it might be a source of annoyance to the sick person, the family and the attending physician. Much good, however, would result, in my opinion, by such a broadening of the scope of sanitary work, without causing annoyance or being detrimental to any one. I should like, however, to point out that more than a year ago the Board of Health of New York City in the revision of its sanitary code included a number of new sections in relation to the infectious diseases, covering to a large extent the diseases above mentioned. These sections, with the accompanying notes, read as follows:

INFECTIOUS DISEASES.

Sec. 133. It shall be the duty of every physician to report to the Department of Health, in writing, the full name, age and address of every person suffering from any one of the infectious diseases included in the list appended, with the name of the disease, within twenty-four hours of the time when the case is first seen:

A. *Contagious* (very readily communicable): Measles, rubella (rötheln), scarlet fever, variola (smallpox), varicella (chicken-pox), typhus fever, relapsing fever.

B. *Communicable:* Diphtheria (croup), typhoid fever, Asiatic cholera, tuberculosis (of any organ), plague, tetanus, anthrax, glanders, epidemic cerebrospinal meningitis, leprosy, infectious diseases of the eye (trachoma, suppurative conjunctivitis), puerperal septicemia, erysipelas, whooping cough.

C. *Indirectly Communicable* (through an intermediary host): Yellow fever, malarial fever.

Note.—In this provisional classification of the infectious diseases, arranged for practical purposes, the most readily communicable of these diseases, embracing the exanthemata and typhus fever, have been placed in a group by themselves and called contagious. This has been done with a view to emphasizing a distinction, which is not only of scientific significance, but of practical importance, in dealing with the sanitary features of administration. This distinction is furthermore of importance because it avoids the misunderstanding and alarm frequently caused by including in the same class the very readily communicable diseases (such as smallpox), and the much less communicable diseases (such as tuberculosis), which require very different sanitary measures for their control.

Sec. 134. It shall be the duty of the commissioners or managers, or the principal, superintendent or physician, of each and every public institution or dispensary in this city, to report to the Department of Health, in writing, the full name, age and address of any person suffering from any one of the infectious diseases included in the list appended, with the name of the disease, within twenty-four hours of the time when the case is first seen:

A. *Communicable:* Influenza, lobar pneumonia, bronchopneumonia, infectious diseases of the gastro-intestinal canal (dysentery, cholera morbus, cholera infantum, summer diarrheas of infants).

B. *Parasitic Diseases of the Skin:* Scabies, tinea tonsurans, impetigo (contagious), favus.

Note: In this list of diseases reporting is required by the department of health in order that data may be obtained for general and special investigation of the modes and sources of infection and as to the prevalence and distribution of these diseases. The Department of Health does not propose to exercise a sanitary surveillance in these cases, but desires information with a view to the ultimate removal or improvement in the conditions which foster them. Notification is required in certain of these diseases because of the liability to their extension among children in the schools.

It will be noted, first, that two main groups of diseases are specified. In the first group, including the more readily communicable diseases, and some others which are not so regarded, registration is compulsory in all cases coming under the observation either of a private attending physician or an institution. These are separated for convenience under three heads: (*a*) The contagious or very readily communicable; (*b*) the communicable, including diphtheria, typhoid fever, Asiatic cholera, tuberculosis, and a number of others, and (*c*) the indirectly communicable, including only two diseases —yellow fever and malarial fever—which are transmitted solely through an intermediary host. In these three classes compulsory registration is required because in all of the diseases in these classes preventive measures, properly executed, are certainly efficient to a very large extent. As to the propriety of the compulsory registration of all of the diseases included under the first heading, "The contagious or very readily communicable diseases," I assume that there can be no reasonable difference of opinion. Measles, rötheln, scarlet fever, varicella, variola, typhus fever and relapsing fever, certainly without question, should be reported to the sanitary authorities. The necessity for reporting rötheln and varicella rests more in the danger of confusion of these diseases with measles and varioloid, respectively, than because of the importance of the diseases themselves. Our experience in New York has shown again and again that outbreaks of smallpox have resulted from the failure of inexperienced physicians to recognize mild cases, these having been mistaken for varicella and treated as such. Every case of varicella occurring in the city must, therefore, be reported, and all cases occurring in adults are immediately seen by a trained diagnostician. I say all cases of varicella in adults, because experience has shown that very frequently varicella in an adult is a mild case of variola.

In the second class, called simply "the communicable diseases," there might be some question as to the propriety of the reports in some instances. There would be none, however, with regard to diphtheria, typhoid fever, Asiatic cholera, plague, tetanus, anthrax, glanders and leprosy. All of these diseases are under some conditions communicable and of the greatest importance, yet they are much less communicable than the first class, the contagious.

There can not now be, nor can I conceive that there ever will be again, any serious question as to the necessity or propriety for the registration and sanitary surveillance of tuberculosis, although this has been a subject of very bitter dispute, and although this disease has come actually under the close supervision of the sanitary authorities in only three or four cities in the United States, and of practically none in Great Britain or on the Continent. Pulmonary tuberculosis was included in the list of communicable and reportable diseases by the New York City Board of Health ten years ago, and the measures adopted for its surveillance have been gradually extended and the lines for its restriction have been drawn closer and closer as each year has passed. Some doubt, however, might properly arise as to the necessity of the inclusion of other forms of tuberculosis than pulmonary tuberculosis in the registration returns, because for the most part these other tubercular diseases are not communicable, or very slightly so. Bone, joint, intestinal and gland tuberculosis are practically never sources of infection in other persons, but cases of tuberculosis of the types mentioned indicate the previous exposure to infection of the individual, and they thus point out a probably infected site or family, concerning which the sanitary authorities should have information. Such cases may also disclose unrecognized instances of pulmonary disease. Furthermore, knowledge of all cases is absolutely essential to a comprehensive recognition of the extent and prevalence of the infectious disease, *tuberculosis*. During the past year measures to ensure the registration of tuberculosis in all its forms have been adopted in New York.

The importance of the registration of epidemic cerebrospinal meningitis arises not so much because of the evidence of its communicability as because of the importance of fuller information as to the conditions under which it arises and becomes disseminated. We have in New York City just been passing through an epidemic of this disease, the first serious one for thirty years. During the month ending May 15 more than 300 deaths occurred in New York City from this cause.

The infectious diseases of the eye—trachoma and suppurative conjunctivitis—should be included because of the importance of the adoption of preventive measures in the public schools. Few persons had any conception of the great prevalence of these diseases of the eye in the public schools of New York until after the Department of Health adopted some comprehensive measures for their surveillance. Such a vast number of cases was found that the Board of Health was forced to establish special dispensaries and provide special hospital facilities for their care. Only within a few weeks a second hospital and dispensary has been opened, and in the original one in connection with Gouverneur Hospital an average of about 500 patients a day were treated during the year 1903, and nearly 5,000 patients were operated on for trachoma.

Puerperal septicemia should be included in the registration returns because modern aseptic midwifery has shown that in most instances this is a strictly preventable disease, and excepting rare cases of difficult or prolonged labor, its occurrence may be regarded as the result of uncleanliness, negligence or incompetence. The registration and the investigation of these cases by the sanitary authorities should soon result in the exclusion from practice of incompetent midwives, restrict the work of the criminal abortionist, and foster the practice of aseptic midwifery.

No one, I fancy, would seriously question the propriety of including erysipelas and whooping cough in the registration returns. So far as this country is concerned I assume that typhus fever, Asiatic cholera, plague, leprosy and yellow fever are diseases which will never again call for anything more than occasional or emergency measures for the disposal of isolated cases or small groups of cases. But with reference to one disease in the third class, i. e., malarial fever, some remarks may be in point to show the advantages which are likely to result from the interference of the sanitary authorities. We now all believe that malarial fever is not only an infectious disease and indirectly communicable through an intermediary host, but that it is also distinctly preventable.

The registration of cases of malarial fever should be required, not because close surveillance of individual cases is necessary, but because the sanitary authorities should know where the sites of infection are, where the breeding places of the anopheles mosquitoes are to be found, in order that they may adopt proper means for determining the cause of such areas of infection and the proper measures for their removal. In certain sections of New York City investigation has shown that in some instances almost every person living within certain small areas has suffered from malarial fever during the spring and summer months of a single season. Such outbreaks are without any question the result of local remediable unsanitary conditions, which furnish the breeding places for the mosquitoes. But without special information as to the existence of the cases, only to be obtained through the registration of malarial fever, knowledge of the presence of much unsanitary conditions and their removal, may become difficult or impossible. The surveillance in their homes of the individual cases reported is of course not contemplated. That conditions similar to those found in New York exist in other communities, I have no doubt.

Section 134 of the Sanitary Code of New York, covering the second group, deals with infectious diseases of a somewhat different type, and in these the Sanitary Code requires the reporting to the department by public institutions of all cases coming under their observation; but it only requests physicians to report them and does not require such reporting.

Class (*a*) in this group includes some of the more important acute infectious diseases of the upper respiratory tract, namely, influenza, lobar pneumonia and bronchopneumonia, and certain of the more common acute infectious diseases of the gastro-intestinal canal, namely, dysentery, cholera morbus, cholera infantum and the summer diarrheas of infants.

The acute diseases of the respiratory tract referred to should, in my opinion, be registered, because they are infectious, because they are of prime importance as causes of death, and in order that general and special investigation may be instituted for the collection of data bearing on the modes of infection and the sources and causes of their prevalence and their distribution. New York City has during the last winter experienced the greatest prevalence of these diseases which it has had for many years. In the first four months of the year more than 6,000 deaths occurred from influenza, lobar pneumonia, bronchopneumonia and acute bronchitis.

I firmly believe that these diseases can be to a very considerable extent prevented, but the means and the methods are yet to be determined, and it is hoped that registration will assist in the acquisition of knowledge for the attainment of this end.

A large new field has just been opened by recent observations with regard to the specifically infectious character of many of the cases of summer diarrhea and dysentery, both of infants and of adults. The results of the investigation of the sanitary authorities in recent years in many large cities have shown in the most conclusive way that these diseases are to a very large extent preventable, and it seems probable, or at least possible, from recent investigations, that some forms at least are preventable and curable by the use of a specific curative serum.

Investigations in New York and other localities have shown that serious outbreaks of diarrhea and dysentery have occurred in various institutions and in local areas which were probably, if not certainly, preventable, but concerning which the sanitary authorities have had no information. It seems evident, therefore, that these diseases should be made notifiable. A practical difficulty in this connection exists in the lack of definiteness as to what cases should be included and how the differentiation is to be made between the diarrheas due to simple digestive disturbances and those of a more serious nature caused by infection. This, however, is a matter for further investigation.

Notification of the parasitic diseases of the skin should be required chiefly because of the liability to the extension of these diseases among children in the public schools.

There are certain very large and important questions of prophylaxis connected with the prevalence of typhoid fever and the milk and water supply of our large communities. The occurrence of great outbreaks of typhoid fever, such as the epidemics at Ithaca, N. Y., and Butler, Pa., during the last year, the prevalence in Philadelphia, Pittsburg and some other cities of the United States and the extensive distribution in the rural districts, constitute a disgrace to American preventive medicine and should arouse the sanitary authorities, the medical profession and the people to the provision of efficient measures and the enactment of suitable legislation for its prevention.

The annual cost of typhoid fever in sickness and death throughout the United States would be computed in terms of tens of millions of dollars. All of this loss we know is certainly preventable. If only a small portion of the annual outlay made by the country for sickness and death from this cause were expended in the education of the people as to the cause and the methods of prevention of this disease and the provision of proper water and sewerage systems, typhoid fever might soon become a rare affection. Unfortunately the city sanitary authorities are often almost powerless in this matter, as their jurisdiction does not extend over the watersheds which supply with water the people under their care, and a supervision by them of the sources of the milk supply is also frequently absolutely impossible.

In New York City detailed investigations of all the cases of typhoid fever occurring within the city limits were instituted several years ago and have been continuously carried on. These show that at least 25 per cent. of the cases occurring in the city have *certainly* received their infection outside of New York City, and a considerable percentage more have *probably* received it outside. Five or 6 per cent. are the result of contact with other cases, and the remainder are in all probability almost wholly the result of infection through milk or oysters. Some more comprehensive measures are urgently demanded to extend the jurisdiction of the authorities in the supervision of the supplies of milk and oysters and other foods.

A serious objection which may be urged against the adoption of the measures here recommended in regard to the registration of many infectious diseases is the increased labor thrown on physicians, which their enforcement would involve. The question may properly be asked: Whether the sanitary authorities in the interest of the general public may call on the medical profession for the expenditure of so much time and labor without making any compensation in return. There are 35 diseases included in the New York list. The English authorities pay a fee for the notification of each case of infectious disease, and I believe that this course might properly be pursued in this country; but this has not been the custom here, and the authorities generally are not now provided with the funds necessary for this purpose.

When the Department of Health of New York City established its bacteriologic laboratories in 1892, measures were adopted to make some return to physicians for their interest and labor in connection with the sanitary surveillance of the infectious diseases. A systematic plan was then inaugurated, and has since been consistently followed, to secure their co-operation, by offering free bacteriologic examination in the diagnosis and surveillance of various forms of infectious disease. This was first applied to Asiatic cholera in 1892, during the outbreak in New York Harbor, and has since been extended to all of the diseases in which existing scientific knowledge made it possible, cerebrospinal meningitis being the latest disease added to this list. The establishment of this system of free bacteriologic examinations in the diagnosis and surveillance of the infectious diseases, and the provision of facilities throughout the city for the collection of specimens and the sending of reports to physicians, constituted an entirely new departure in sanitary work and has been of the greatest value. The example of New York has been followed by the sanitary authorities in most of the large cities of this country, by many state authorities, and by authorities generally, in Great Britain and to a certain extent on the Continent. These examinations constitute the return which the authorities here have made to physicians for the reporting of cases and for their assistance and co-operation in their care. This return has a very considerable money value, when we remember that for such examinations the usual fee is $5, and as physicians can not, as a rule, make such examinations themselves, they must work without the assistance thus afforded, unless they appeal to the regularly constituted laboratories.

What now are the possibilities of preventive medicine as concerns the larger centers of population? In answering this question we may first take as the basis of our reply the conditions found in some of the large cities with the lowest death rates, or still better, the conditions found in some healthy rural districts. In considering the crude death rates, as ordinarily reported, however, one must not ignore the influence of the sex and age distribution of the population on the death rate. As is well known, the death rates in the periods of life between 5 and 45 years of age are very low, and the death rate among women is lower than among men. If, then, in a city there is a relative excess of the population in the middle periods of life, or an unusual preponderance of women, we may have a crude death rate which seems very low, but which when corrected may be relatively high. For example, the death rate of New York City, as corrected by the English life tables, would probably be at least three points higher than it is. For 1894 the gross rate was 22.76, and the rate corrected by the English tables was 26.46. The corrected death rate of some of the large, rapidly growing Western cities would probably be five or six points higher than the crude death rate reported. The death rate of London at present averages about 17 per 1,000, and when corrected about 18.5 per 1,000, while the Berlin death rate is somewhat lower than this. The crude death rate of Surrey, a healthy rural district in England, is 14 and a fraction, and when corrected would probably be 15.

We can hardly use for a basis of comparison the conditions in any of the cities of this country with very low rates, because the rates have not been corrected, and the basis on which they are calculated can not always be accepted as correct. Taking all the facts together, and judging of the duration of human life as we know it, we may accept a corrected death rate of 14 or 15 in a large city as a goal toward which preventive medicine should strive and hope to achieve. If we consider the question from another point of view, as to what is possible in the reduction of the death rate from distinctly preventable diseases, we would reach a conclusion not unlike the previous one.

In New York City it may be assumed that the present tubercular death rate of 2.7 may, under proper surveillance, with certainty be reduced to 1.2, and 1.5 points would thus be subtracted from the crude rate. The diphtheria death rate, already reduced 65 per cent. by the use of antitoxic serum, should certainly be reduced to one-third of what it is at present; it is now about .6 per 1,000 population. Similar reductions should be possible in the death rate from typhoid fever, measles and scarlet fever. The diarrheal diseases of infants have already been reduced in the last twelve years to one-half of their former prevalence, and should still be reduced more than 50 per cent. Thus more than 3 points may be subtracted from the crude rate in New York, which in 1903 was 18.18. The rate would then be 15+. The rate for 1903 was the lowest in the history of the city.

The most fatal affections with which we have now to deal in New York are the acute respiratory diseases, including influenza, lobar pneumonia, bronchopneumonia and acute bronchitis. The average death rate from this group of diseases now exceeds 3 per 1,000 of the population, and in years when there is an epidemic prevalence of these diseases the death rate may be 4 or more, as seems likely to be the case this year.

The advances in preventive medicine have as yet not only had no influence in reducing the death rate from this group of diseases, but, on the contrary, there has been a slow and continuous increase. I can not at this moment point out the method or the means by which a reduction is to be brought about, but still I firmly believe that with fuller knowledge such a reduction will become possible in the great cities where these diseases are so prevalent.

Something can be accomplished through the closer sanitary surveillance of the occupations and conditions under which the lower classes work, especially the noxious trades. Something, too, may be done through a closer supervision of foods to ensure their purity and freedom from adulteration.

A very difficult problem arises in connection with the diseases of the circulatory apparatus and the kidneys. My investigations have shown that in New York City a large increase has taken place, due to these causes, during the last twenty years. The acute respiratory diseases, cancer and diseases of the circulatory apparatus and the kidneys are the only important causes of death which have shown an increase during this period. The increase in cancer amounts to about 15 per cent., and the increase in the acute respiratory diseases amounts to about 15 per cent., while the increase in the diseases of the circulatory apparatus and kidneys combined equals about 40 per cent. In making this statement I have taken fully into consideration the possible influence of greater accuracy in the death returns, i. e., the inclusion formerly of these under other causes of death; but after making all allowances, it seems to me without question that an increase equaling 40 per cent. has taken place.

A very important sanitary problem is here presented to the health authorities. What are the factors in the lives of the inhabitants of our large cities (for I have found that similar increases, less extensive, however, have taken place in London, Paris and Berlin) which have caused such a remarkable increase in the prevalence of these affections, and how are these factors to be removed?

The time at our disposal does not permit of more than this elementary and cursory review of the work in preventive medicine. Sufficient facts have, however, been adduced to show how great have been its achievements, and some of the directions have been indicated in which its scope should be extended. With such extensions, and many others not mentioned, the future possibilities of preventive medicine seem to be even greater than the past achievements, for almost every development in bacteriology opens up a new field of work for the sanitary authorities.

THE PROPHYLAXIS OF TETANUS.*

S. C. STANTON, M.D.

CHICAGO.

Before taking up the consideration of the prophylaxis of tetanus, it may be well briefly to discuss the disease and to give some statistics regarding its prevalence and mortality.

ETIOLOGY.

Tetanus is defined as an acute, specific infective disease, characterized by involuntary tonic muscular spasms, tending to become generalized and with paroxysmal exacerbations from time to time. The causative micro-organism is the tetanus bacillus which, having gained entrance to the body, elaborates a virulent toxin and this, acting on the motor cells of the spinal cord and medulla, increases their irritability and induces the spasm.[1]

The tetanus bacilli or their spores are most commonly present in garden soil, street sweepings, stable manure and the feces of herbivorous animals.

In almost all cases the virus can be shown to have entered the body through a wound, and deep punctured wounds are the most likely to be followed by tetanus. The disease is more frequent in negroes than in white persons, and is more prevalent in the tropics than in the temperate zone.

PREVALENCE.

The distribution of tetanus in the various states, as shown by the United States census for 1900, is interesting. During that year 1,664 deaths were recorded; 185 of these were in Louisiana; 147 each in New York and Pennsylvania; 125 in Texas; 90 in Illinois; 76 in Ohio; 74 in Florida; 61 in Alabama; 56 each in Indiana and New Jersey; 51 in Virginia; 48 in Maryland; 46 in Georgia; 43 in Missouri, and 41 in Tennessee. Louisiana, with a census population of 1,381,625, heads the list with 185 deaths.

The prevalence of the disease by months has been investigated by Dr. H. Gideon Wells,[2] Chicago, who has found that the curve of deaths takes its upward start in May, reaching its maximum in July, and thence declining to October. These figures are for 1900. In 1901 there were relatively few deaths from tetanus in July, when the usual augmentation occurs. In 1902 the curve again reached its summit in July, but with a mortality of only 15 as compared with 26 in 1900.

---

* Read before the Mississippi Valley Medical Association at its meeting in Memphis, Oct. 9, 1903.

[1] Encyclopedia Medica. vol. xii: "Tetanus," by W. T. Ritchie, M.D., Edinborough.

[2] Fourth of July Tetanus, American Medicine, June 13, 1903.

The deaths from tetanus in Greater New York reached a maximum of 21 in July, 1899, the greatest totals in any other month of the year being 5 in June and 4 in September, the total deaths for the year being 38. In 1900, 13 deaths occurred during July and 5 in June out of a total of 33 for the year. In 1901 there were only 5 deaths in July, and this number was exceeded in April and October, in each of which months 6 deaths occurred.

The statistics of the census of 1900 show that 222 deaths from traumatic tetanus occurred between the ages of 10 and 14; 149 between the ages of 5 and 9; 117 between the ages of 5 and 19; 84 between the ages of 20 and 24; 79 between the ages of 25 and 29, and 77 between the ages of 30 and 34. As far as these statistics go, it appears that the greatest mortality from this disease occurs before the age of 19, and that the mortality below the age of 14 is about three times as great as that between the ages of 15 and 19.

The Journal of the American Medical Association has taken up exhaustively in its August 9 (1903) issue a subject which must interest the American physician deeply—namely, the tetanus following the Fourth of July celebration. Its statistics show an appalling and unnecessary slaughter of the innocents. The total number of deaths due to Fourth of July injuries is 466, of which 406 were due to tetanus. Pennsylvania heads the list with 86, and is followed by Ohio with 77, Illinois with 59, New York with 41, Michigan with 31, Missouri with 29, Massachusetts with 17, Minnesota with 15, Iowa with 16, Indiana with 14, Kansas with 13, and New Jersey and Wisconsin with 10 each. With but few exceptions, the victims were small boys.

The cause of Fourth of July tetanus has been supposed to be the presence of tetanus bacilli in blank cartridges, but this can not be considered as proved, as only one of the several investigators detected tetanus bacilli in blank cartridges or wads. The bacillus has, however, repeatedly been found in the dust of the streets where tetanus has been prevalent.

As a result of the investigations, we may conclude that there is no convincing evidence that blank cartridges contain tetanus bacilli, except as a rare contamination; there is, on the other hand, ample evidence that tetanus bacilli are present in street dust and on the persons and clothing of the injured, and the most reasonable conclusion is that of La Garde, Wells and other investigators, that the organisms are carried into the wounds from the surface at the time of the accident.

PROPHYLAXIS.

As the greatest mortality during the year is observed about the time of the national celebration on the Fourth of July, it naturally follows that in the prophylaxis of tetanus this important factor should not be omitted.

The prophylaxis of tetanus may be considered under five heads:

1. The enforcement of existing laws regarding the sale of toy pistols and other dangerous toys. In most cities and in some states there are already laws, supposedly in effect, which prohibit the use of firearms and the setting off of fireworks. At and around the time of the Fourth of July, however, these laws are almost invariably forgotten, or at least their enforcement is criminally neglected. A striking example of the results of enforcement of ordinances regarding the use of explosives is furnished in Washington, and this city does not show an increased mortality from tetanus in July.

2. The enactment of laws by Congress, state legislatures and municipalities prohibiting the manufacture and sale of toy pistols, blank cartridges, dynamite canes and caps, cannon crackers, etc. Spurred on by the terrible aggregate of deaths which followed the Fourth of July this year, several medical societies have already recommended the adoption of ordinances which shall avert the possibility of a repetition of this heavy total in after years. Several city councils have also drafted and adopted ordinances on these lines, but without enforcement such ordinances are of no effect, and the slaughter will be continued.

3. The open treatment of all wounds, however insignificant, in which from the nature or surroundings there is any risk of tetanus. By open treatment is meant the free opening of the wound, cleansing from all foreign substances, swabbing thoroughly with 95 per cent. carbolic acid, followed by open dressing of the wound, with the institution of drainage. During the preparation of the grounds and buildings for the World's Fair in Chicago, at which time the conditions for the development of tetanus were exceedingly favorable, by reason of the excavation, turning over of black soil, etc., more than 1,500 cases of punctured, incised and contused wounds were treated by the surgical staff on the grounds; in most instances the patients returned to work in two or three days, and in no case did tetanus develop.

4. The immediate use of tetanus antitoxin in all cases of Fourth of July wounds, wounds received in barn-yards, gardens or other places where the tetanus bacillus is likely to be present or tetanus infection to occur. The neutralization of any toxin still in the blood and not yet fixed in the nerve-cells can be effected by the injection of from five to ten cubic centimeters of tetanus antitoxin. This injection should be made as early as possible, and while its use may seem superfluous in cases in which wounds have been treated immediately and thoroughly, still it does no harm and gives additional assurance to the patient.

5. The injection of tetanus antitoxin as soon as tetanic symptoms become manifest. When the infection has so progressed that tetanus symptoms appear, the use of antitoxin is a forlorn hope, for, as Wells says, "a patient who has just developed symptoms of tetanus is not just developing the disease, but is dying of it." Although the results from the injection of tetanus antitoxin after the development of tetanus show thus far that only an exceedingly small percentage of recoveries take place, still, when the almost certainly fatal outcome of the acute form of the disease is considered, the use of tetanus antitoxin is made justifiable.

In the presentation of this subject I am aware that I am not submitting anything original; but I desire earnestly to urge on the members of this association the advisability, or even the necessity, of carrying on the propaganda begun by The Journal of the American Medical Association and continued by the medical and lay press. Heretofore there has been much excitement regarding the matter of Fourth of July injuries for a month or two following the celebration, but then, with the lapse of time, the appreciation of the needlessness of this mortality lessens, and until public attention is directed to the next series of deaths little thought is taken by the majority of the people. Physicians should take on themselves the burden of keeping the public aroused to the appalling mortality which succeeds a supposedly peaceful celebration, a mortality which with proper and thorough treatment, and with the enactment of sufficient laws, might be practically abolished. If the profession of the country would take united action in this matter, the mortality of 406 from tetanus following Fourth of July accidents alone might, in 1904, be reduced to zero. When it is remembered that by far the greatest number of deaths occurs in individuals who have not yet reached the age when they are able to distinguish between things dangerous and things safe, the responsibility of the physician as regards instruction of parents of the dangers to be feared, and in the precautions to be observed and the treatment to be carried through, is immeasureably increased. The saving of 400 lives from a burning or sinking ship would be considered well worth the doing. How much more important is the saving of hundreds of lives of the innocents from an unnecessary and horrible death!

PROSTATECTOMY.

REPORT OF 51 CASES OPERATED ON FROM MAY 6, 1901, TO FEBRUARY 26, 1904.

JOHN B. MURPHY, A.M., M.D.
CHICAGO.

(*Continued from page 1413.*)

TECHNIC OF PERINEAL OPERATION.

The incision is made in the median line of the perineum to within three-quarters of an inch of the anal orifice. The latter limbs of the incision now diverge from each other in an oblique direction on each side of the anus to the margin of the ramus and backward to the level of the posterior anal corrugations. The scalpel is used to divide the superficial perineal fascia, and the handle is then used to separate the muscle fibers in each lateral incision down to the deep perineal fascia and capsule of the prostate. This leaves the median raphe and the tissues for one-half inch on each side of it intact. By following this plan and always separating the muscular fibers in a backward and outward direction, the rectum is safe from injury.

After the completion of the lateral incisions the index finger of the left hand is inserted into the rectum and, with the scalpel, the central bridge of tissue mentioned above is divided close to the wall of the rectum down to the capsule of the prostate. The object in keeping close to the rectal wall in this last step of the operation is to avoid the hemorrhage which would occur if the corpus spongiosum were cut. In the tissues thus divided there are few vessels and practically no blood is lost.

The rectum is now pushed a little farther posteriorly, and the deep perineal fascia and capsule of the prostate are divided transversely with the blade of the scalpel. In my early operations I made the capsular divisions on each side of the median line and parallel with the raphe, but as the raphe must be eventually divided I now make one transverse incision across the entire capsule dividing the central septum. The handle is again used to free the capsule from the prostate on both sides sufficiently to allow the insertion of the index finger which liberates the capsule from the lateral lobes and posterior isthmus back to the bladder wall. A short, broad Sims' speculum is then inserted and used to displace the rectum and capsule backward. One four-pronged cat's paw hook retractor is now put in each lateral lobe as far back toward the bladder as possible, and used to draw down the prostate *en masse*. A long curved scissors now divides transversely the posterior urethral wall anterior to the prostate. The division is then continued on each side through the lateral attachment of the anterior isthmus to the posterior boundary of the prostate. This boundary can be readily recognized as the urethra is open. The prostate is now free from all of its connections anteriorly and laterally, and is removed entire when the posterior urethral wall behind the prostate is divided transversely.

It will be seen from the above description that all of the posterior prostatic urethra to the sphincter vesicæ internus is removed with the prostate.

This particular method of separating the prostate from its attachment to the bladder makes the procedure practically a surface operation from beginning to end.

After the last step described above is completed, the sound is withdrawn and the finger passed into the bladder to examine its interior and to determine whether or not stones are present or to detect enlargements of the middle lobe or pedunculated growths from the lateral lobes. If the latter are found they can be readily removed without lacerating the sphincter.

The lateral edges of the prostatic urethra are now brought together to form a new canal, by means of a continuous catgut suture, which is inserted from behind forward. Only space enough is left for the drainage tube which passes into the bladder. A loose packing of bismuth subiodid gauze is now put in the cavity of the capsule, the end of the gauze with the tube protruding through the left angle of the incision. The divided perineal muscles are sutured back into position with catgut and the skin approximated with silkworm gut.

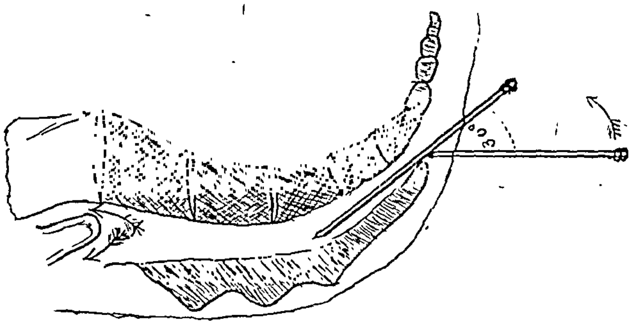

Fig. 10.—Showing needle inserted through hiatus sacralis into sacral canal for the purpose of producing analgesia by epidural injections of cocain solution.

The tube is removed from the bladder four to ten days after the operation, depending on the degree of cystitis present. The gauze is removed on the third day after the operation and the wound allowed to close.

SUPRAPUBIC PROSTATECTOMY.

In this operation we have followed the plan of Freyer, that is, of splitting the bladder mucosa over the lateral lobes, inserting the finger beneath the mucosa and enucleating the prostate—bringing with it the prostatic urethra. While it can be accomplished and is indicated in cases where the prostate is high up and firmly fixed, it is not at all so clean-cut and precise a procedure as is the perineal operation described above. It has the disadvantage of requiring irrigation in order to keep the bladder aseptic. It has the advantage, however, of assurance against perineal fistula, but the perineal fistulæ leak only during urination, while the ventral fistula following the suprapubic operation leaks more or less continuously, and from our experience, the healing is no more rapid.

The surprising feature of the suprapubic operation after this method is that stricture is not more common, and it does seem as though incontinence should occasionally result—two problems which time alone will elucidate.

In the perineal operation, the wall of the bladder should not be divided or torn. When an intravesical lobe exists, the mucous membrane covering it should be split and the lobe enucleated from within the bladder, thus preserving the vesical muscles. The posterior wall of the prostatic urethra should be removed. The urethra should never be opened primarily, and the prostate should never be shelled away from the bladder from before backward, but always from behind forward, dividing the isthmus as the prostate rolls away from the bladder. To favor this I have used the ordinary deep lateral retractors, a Sims' speculum as a posterior retractor and the hooks as shown in Figure 9. The hooks are utilized (1) to draw the prostate into the field and retain it there; (2) to evert the prostate while it is being detached from above downward from the bladder wall. I find great advantage in using the handle of the scalpel down to the prostate on each side before dividing the septum. It insures safety to the rectum. The sound is the only instrument needed to press the prostate down into the field, and it also answers as a guide to the location of the urethra.

It is entirely unnecessary in the operation of prostatectomy to remove the whole anatomic structure, as is claimed by Freyer, as the anterior portion of the prostate, or isthmus, never shows any material enlargement and never produces urinary obstruction. It can, however, be as easily removed, if the entire enucleation be desired, by the perineal as by the suprapubic route if the hook retractors are used as shown in the drawing, and the whole prostatic urethra sacrificed. The hemorrhage is very much less by the perineal than by the suprapubic route.

The arched or Y-shaped incision offers the best view of the underlying structures, and the claim that there is excessive mutilation of the tissues by these incisions is not sustained by the facts. No matter how large the skin incision, the opening within can not be less than the size of the prostate; therefore, why endeavor to bring a large prostate out through a buttonhole in the skin? Why do surgery in the dark when open work can be as easily and safely performed?

REMARKS.

The results are more gratifying as time progresses and we become more familiar with the technic in the complicated and difficult cases, but my first case has not been excelled by any subsequent one in its result.

The capsule of the prostate should be displaced backward with the rectum to insure the integrity of the latter.

The hemorrhage was quite profuse in two cases. This was controlled by placing hemostatic forceps on the bleeding points, and allowing them to remain for forty-eight hours, as in vaginal hysterectomy. The packing with subiodid of bismuth gauze is sufficient to control venous hemorrhage.

The permanent catheter has been abandoned in my later cases. It is not only unnecessary, but injurious. The perineal drain is retained until the urine is practically free from pus, usually from three to eight days. The bladder is not usually irrigated.

It is important to remove the redundant prostatic urethra, to avoid the tendency to perineal fistula, and the opening should be closed with catgut sutures down to the drainage tube.

CONCLUSIONS.

1. The perineal route gives the best ultimate result.
2. It is accompanied by less danger than the suprapubic or Bottini operations, as regards (*a*) hemorrhage; (*b*) sepsis; (*c*) injury to the neighboring structures; (*d*) life. In fleshy patients the hemorrhage is more profuse, repair slower and the urethral fistula lasts for a longer time.
3. The drainage is excellent, and favors rapid restoration of the bladder to its normal condition.
4. The period of wound repair is much shorter than by the suprapubic route. All cases had primary union down the drainage tube.
5. The vesical control is almost uniformly good.
6. The sexual power is usually destroyed.
7. The relief of vesical irritation is great, and the frequency of urination is reduced to about normal.

In submitting this paper the chief purpose is to show the final results from the patient's standpoint. It is a settled fact from the force of numbers—in the hands of many operators—that the mortality from the operation of perineal prostatectomy *per se*, is practically *nil*. The remaining questions are: 1. Does the operation relieve the patient from his suffering? 2. Has he assurance that he will not have to return to the catheter? 3. Has he urinary control? 4. Is he free from the danger of stricture of the urethra? 5. Is he comparatively free from the dangers of secondary renal changes? 6. Is there danger of a prolonged or permanent urethral fistula? 7. Will he suffer from repeated and annoying attacks of epididymitis?

In order to obtain exact and definite information on these points the following list of questions was sent to each patient by Dr. James M. Neff, and the answers, so far as they have been received and indicate trouble, are inserted in the individual history, so that the reader is able to draw his own conclusions as to the results of the operation.

1. Is wound below entirely healed?......If not, when did it open and what is the character of the discharge from it, urine or pus?..................If urine is discharged from wound does it come constantly or only when the bladder is emptied?..........................

2. Do you have any pain in wound, bladder or urethra?..... If so, where and how severe is it?........................

3. How long can you hold the urine during the day?........

4. How long can you hold the urine during the night?.......

5. Have you perfect control over the urine? .... If not, to what extent have you control?.. ....

6. Have you used the catheter since operation?........... If so, how often, etc.?........... ....

7. Is the sexual function impaired?...................... If so, to what extent?..................................

8. How is your general health as regards weight, ability to attend to business, etc.?................................

9. Please state anything else of interest not mentioned above.....................

Case 1.—Mr. E. W., aged 55; occupation, financier. Admitted to Mercy Hospital May 16, 1901.

Personal History.—Had specific urethritis; stricture followed; cured.

Present Illness.—Three years ago he began to suffer from increased frequency of micturition, which has continued ever since. Has used catheter and vesical lavage for 2 years. Residual urine, 3 ounces. He has been entirely incapacitated for work.

Examination.—Urine shows a trace of albumin, some blood and a large amount of pus. Urea 1.8 per cent.; specific gravity 1024. Prostate much enlarged; left lobe the larger. Patient emaciated and very neurotic.

Operation.—May 18, 1901: Regular technic used. Rubber catheter inserted through penis. Uneventful recovery; left hospital June 26, 1901. Feb. 25, 1903, perineal wound has remained closed. Perfect control of bladder. Holds urine five or six hours during day and is not obliged to get up to urinate during the night. No pain in the wound, bladder or urethra. Urine free from pus. Sexual function impaired. General health excellent.

Case 2.—Mr. J. S., aged 54; merchant; married. Admitted to Mercy Hospital July 3, 1901.

Present Illness.—For past seven years patient has been troubled with painful urination and inability to empty bladder. Two years ago he began catheter life, continuing it for thirteen months. Resorted to catheter again this spring and has used it since.

Examination—Prostate is very much enlarged and almost fills the pelvis. Urine shows trace of albumin and pus in quantity. Residual urine, 3½ ounces.

Operation.—July 13: Regular technic. Catheter inserted through the penis into bladder. Patient discharged from hospital August 22, with full control and practically no pain during urination.

March 30, 1903: Wound has remained healed. Has complete control over bladder. Can retain urine as long as he desires, never having to get up at night. No pain in the wound, but has slight feeling of contraction at the close of the act of micturition. No blood or pus in the urine and but a small amount of mucus. Sexual function absent.

Report March 29, 1904: Patient states that result of operation is perfect. General health excellent. Sexual function absent.

Case 3.—Mr. A. J., aged 67; merchant. Admitted to Mercy Hospital Aug. 24, 1901.

Present Illness.—Has suffered for two years with frequent desire to urinate and vesical tenesmus. Has used catheter at intervals for past nine months.

Examination—The prostate is very much enlarged. Stone detected. Urinalysis: Acid; specific gravity 1013; a small amount of albumin; urea, 1.4 per cent. Microscopic: Epithelium, a few cells; many red blood cells; pus in quantity. Residual urine, 10 drams.

Operation.—August 25: Regular technic. Stone removed without difficulty. Rubber catheter introduced through urethra into bladder.

Patient discharged from hospital with wound closed, but only slight urinary control, June 26, 1902.

February, 1903, perineal wound has remained closed. He has not complete control of the urine and there is leakage when he moves about and during sleep. He complains of considerable pain in the bladder and rectum. Urine contains pus. Sexual function is entirely abolished This patient has since died of pneumonia. (In latter part of 1903.)

Case 4.—Mr. W. S. M., aged 58; married; farmer. Admitted to Mercy Hospital Nov. 4, 1901.

Present Illness.—Patient fell astride a ridge of dirt eight years ago. Had chills and fever for next twenty-four hours and passed his urine with effort. No blood in the urine or stools. Since that time has had frequent urination and vesical tenesmus especially when on his feet. Was catheterized but once last summer.

Examination.—Prostate enlarged to second degree. Stone detected.

Operation.—Nov. 6, 1901: Regular technic.

Report March 29, 1904: Wound has remained healed. Has occasional pain in vicinity of wound, not severe. Holds urine during day from two to three hours and gets up three or four times at night. Control of bladder good. Has not used catheter since operation. Sexual function impaired. Some pus present in the urine. Has had several small abscesses form in front of anus, but urine has never been discharged from them when they opened.

Case 5.—Mr. P. T., aged 62; retired farmer. Admitted to Mercy Hospital Dec. 2, 1901.

Present Illness.—Since four years ago has complained of frequent urinations, of late eight or ten times during night. Has used catheter several times in past 10 weeks. Severe cystitis for some time past.

Urinalysis.—Sp. gravity 1016; urine turbid; urea 2.4 per cent; phosphates increased; indican present; no casts, some albumin; many pus cells. Bladder was irrigated daily after admission. The prostate much enlarged and lobes seem to fill the pelvis. A stone detected in bladder.

Operation—December 11: Regular technic. Patient left hospital January 18.

Report March 29, 1904: A small sinus remains at site of perineal wound. A little pus is discharged from sinus, but no urine at any time. Complains of some pain in vicinity of this sinus when he sits down. Holds urine during the day about two and a half hours and at night arises about four times to evacuate bladder. Urinary control good, except at night, when there is some leakage through urethra. Used catheter a few times previous to January, 1904, but not since. Sexual function not impaired. General health excellent, better than for years.

Case 6.—Mr. L. D. R., widower, aged 70.

Present Illness.—In September, 1901, had an abscess in prostate which discharged into rectum. Nov. 11, 1901, present attack began, with severe pains in prostate and constant desire to pass water. On November 14 complete retention came on and continued until the 22d. He was catheterized every three or four hours.

Operation.—Nov. 28, 1901: At Sandwich, Ill. Regular technic. Abscess was found in the left lobe.

March 29, 1904: A small perineal fistula persists, through which a small amount of urine is discharged during micturition. Has some pain during passage of urine. Holds urine during day about 2 hours and at night from 1 to 2 hours. Control good. Sexual function impaired. General health good.

Case 7.—Mr. C. G., aged 52; laborer; single. Admitted to Cook County Hospital Dec. 7, 1901.

Present Illness.—Patient is mentally deranged and his statements are not to be relied on.

Examination.—Bladder extends upward above umbilicus. No stricture. Slight urethral discharge. A very much enlarged prostate found.

Operation.—Dec. 20, 1901: Regular technic. The mental condition of the patient remained the same after operation. The perineal wound entirely healed and he had some urinary control. About six weeks after the operation he developed an acute lobar pneumonia and died before he left the hospital.

Case 8.—Mr. H. H,, woodworker; aged 66. Admitted to Mercy Hospital Dec. 16, 1901.

Present Illness.—Has had symptoms of prostatic hypertrophy for 12 years. Has catheterized himself daily since three weeks ago. Residual urine, 5 ounces. He urinates every two or three hours during the day and rises many times at night.

Urinary Examination.—1,500 c.c. in 24 hours; sp. gravity; 1017; urea, 1.5 per cent.; turbid; faint trace of albumin; pus in large quantity.

Examination.—Prostate very much enlarged, particularly on left side. Stone found.

Operation.—January 8: Regular technic. Stone removed. Soft catheter retained in bladder.

Report March 29, 1904: Wound has remained permanently healed. No pain at any time. Holds urine during day for six or seven hours and occasionally gets up once during night. Some times sleeps all night. Urinary control perfect. Has not used catheter since operation. Sexual function lost. General health excellent.

Case 9.—Mr. C. D., aged 67 years. Admitted to Cook County Hospital Jan. 28, 1902.

Present Illness.—About five years ago first experienced difficulty in passing urine. The straining and frequent desire to urinate have persisted to the present time. Urinates about every three hours during the day and night. He commenced using catheter last September and since then has continued its daily use. Right testicle has been swollen for past few days.

Examination.—Prostate only slightly enlarged. Urinalysis:

acid, turbid, trace of albumin; no sugar; pus cells numerous. Residual urine in bladder, four ounces.

Operation.—Feb. 7, 1902: Regular technic. A fold of mucous membrane, forming a sort of valve to the internal urethral opening, was cauterized in the median line. Permanent catheter inserted.

April 16, 1902: He states that the results of the operation have been perfect in every way. At that time he was in the hospital with a fracture of the femur. It has been impossible to locate this patient since date of last report.

CASE 10.—Mr. G., aged 69 years; occupation, farmer. Admitted to Mercy Hospital Feb. 13, 1902.

Family and previous history negative.

Present Illness.—Began 18 months ago with difficulty in starting the urine. Shortly after onset developed an acute retention of urine and had to be catheterized. Has used catheter continuously since August last.

Examination.—Poorly nourished. Prostate only slightly enlarged as regards lateral lobes. The sound in the urethra shows the prostatic portion of the canal pushed far forward, evidently by a large middle lobe. No stone found. Urinalysis: acid, 1011; cloudy; trace of albumin; many pus cells; few red blood cells.

Operation.—Feb. 15, 1902: Suprapubic cystotomy with deep cauterization, by means of the Paquelin cautery, of the middle lobe, where it projected into the bladder. Convalescence uneventful, except that the suprapubic sinus was slow in closing. Patient left the hospital with symptoms relieved and wound healed April 30, 1902.

CASE 11.—Mr. E. G., aged 65 years; farmer. Admitted to Mercy Hospital Feb. 26, 1902.

Present Illness.—About ten years ago patient first experienced difficulty in passing his urine. Two years ago he began using catheter and has continued its use daily ever since. About fourteen months ago a suprapubic cystotomy was performed and the incision was slow in healing. He received no benefit from the operation. Of late he has had to urinate every hour.

Examination of patient showed suprapubic wound entirely healed. Prostate much enlarged bilaterally. Urinary examination: alkaline; sp. gravity, 1016; albumin present; many pus cells; no casts.

Operation.—March 1, 1902: Regular technic. Discharged from hospital April 17.

March, 1903: Perineal wound has remained healed. He has complete control of the bladder and holds the urine for one and a half to two hours during the day and night. Of late he has occasionally used the catheter at night. Complains of some pain in the wound and urethra. Urine contains some pus, but less than before operation. Sexual function abolished. Patient still complains of frequent desire to urinate and inability to empty bladder. He has no stricture, as a large sound falls into bladder.

CASE 12.—Mr. X., aged 78 years, was seen by me in consultation with Dr. Charles D. Lockwood, in Pasadena, Cal., March, 1902. Patient had suffered with the usual retention of prostatic disease for the past four years, most of the time resorting to the catheter for relief. He had several ounces of residual urine. Urine contained some pus; no blood.

Examination revealed a prostate filling the transverse diameter of the pelvic arch.

Dr. Lockwood operated and I assisted.

On March 23, 1903, I saw this patient with Dr. Lockwood. He was looking splendid and said he "did not know he had a bladder." He does not have to get up at night to urinate and goes as long as six hours in the daytime without urinating.

CASE 13.—Dr. F., aged 60 years; physician. Admitted to Mercy Hospital May 10, 1902.

Present Illness—Began with acute retention three and one-half years ago. Since then frequent urinations have continued. Has used catheter once or twice a day for past year.

Examination.—Prostate enlarged, right lobe being much larger than left. Urinary examination: Quantity in 24 hours 2,410 c.c.; acid, sp. gravity 1010; trace of albumin. Microscopic: Many pus cells; no casts.

Operation.—May 14, 1902: Regular technic. Permanent catheter inserted through urethra. Left hospital July 4, 1902.

April 1, 1903: Perineal wound has remained closed and he has complete control of the urine. He holds urine five hours during the day and nine hours at night. No pain in wound, bladder or urethra. Sexual function is abolished.

CASE 14.—Mr. C. D. B., age 66; occupation, farmer. Admitted to Mercy Hospital May 8, 1902.

Present Illness.—For past 7 years patient has had to pass urine frequently, sometimes every hour during the day and seven or eight times at night. Catheter has been used only for past few days.

Examination.—Prostate enlarged, the lateral lobes extending out to rami on each side. Bladder distended to two inches above navel. Urinary examination: Albumin +; no sugar; few granular casts; many pus cells. For four days before operation bladder was catheterized every five hours and ten grains of urotropin given t. i. d.

Operation.—May 14, 1902: Regular technic. Permanent rubber catheter introduced. Patient left hospital June 19, 1902.

Report March 29, 1904: Wound has remained permanently closed. No pain at any time. Has perfect control of the urine and holds it the normal length of time. Has not used catheter since operation. Sexual function impaired. General health excellent.

CASE 15.—Mr. E. S., aged 69 years; farmer. Admitted to Mercy Hospital May 6, 1902.

Family and personal history negative.

Present Illness.—Four years ago had two attacks of renal colic in left side, and after second, passed several small calculi, For the past year has suffered from frequent urination, with considerable pain. Several attacks of acute retention during the last six weeks.

Examination.—Very slight enlargement of the lateral lobes of the prostate. Stone found in the bladder. Urinalysis: Yellow, clear, 1012, no albumin, no pus.

Operation.—May 28, 1902: Suprapubic cystotomy. Two stones removed and the middle lobe of the prostate enucleated. Mucous membrane sutured over the defect left by the removal of the lobe. Patient left hospital June 11, 1902, with the suprapubic opening not entirely healed.

CASE 16.—Mr. W. M. T., aged 60 years. Admitted to Mercy Hospital July 7, 1902.

Present Illness.—Onset twenty years ago with inability to pass urine and pain over the pubes when he attempted to urinate. He has catheterized himself steadily for past six years.

Examination.—The prostate gland only moderately enlarged. Urine: Acid, turbid, albumin trace, no sugar, many pus cells.

Operation.—July 9, 1902: Regular technic. Permanent catheter introduced. Left hospital August 6, 1902.

Report March 29, 1904: Wound has remained permanently closed. Some pain in urethra occasionally. Holds urine during day from one to one and a half hours and at night from one to four hours. Retains urine in bladder without leakage, but must use some force to start the stream. Sexual function impaired.

CASE 17.—Brother A., aged 52 years. Occupation, teacher. Admitted to Mercy Hospital July 18, 1902.

Present Illness.—Patient has had enlargement of the prostate for the past twelve years, the principal symptom of which is increased frequency of urination, both day and night. He has to void his urine every one-half to two hours during the day and every two hours at night. No pain. Never had a catheter passed.

Examination of Patient.—Prostate moderately enlarged and very hard. Examination of urine: Quantity in twenty-four hours, 1620 c.c. Specific gravity, 1015. No albumin; no sugar. Microscopic examination:: Negative. No pus or blood.

Operation.—July 23, 1902: Regular technic. Permanent catheter used. Left hospital Aug. 18, 1902.

March 20, 1903: Perineal wound has remained healed and he has complete control of the urine. He holds urine four hours during the day and four or five hours during the night. No pain. Urine clear. General health excellent.

CASE 18.—Mr. W. P. D., aged 68 years. Married. Occupation, traveling man. Admitted to Mercy Hospital Aug. 12, 1902.

Present Illness.—Began about a year ago, with inability to pass his urine; had to be catheterized. Since that time he has suffered from increased frequency of urination.

Examination.—Prostate enlarged, the enlargement affecting both lobes.

Operation.—Aug. 13, 1902: Regular technic. Patient was discharged from hospital Sept. 23, 1902.

March 30, 1903: Perineal wound has remained healed and he has complete control of the urine. He holds urine from five to seven hours during the day and about six hours at night. Sexual function is abolished.

Report March 29, 1904: Wound has remained permanently healed. No pain. Holds urine during the day from one to two hours and at night from one to three hours. Control of bladder good, except when it becomes distended. Patient's doctor has passed catheter a number of times. Sexual function impaired. General health good.

CASE 19.—Mr. E. J. W., aged 60 years. Single. Photographer. Admitted to Cook County Hospital Aug. 24, 1902.

Present Illness.—For 36 hours before entering hospital patient suffered from very frequent urinations and severe vesical tenesmus. The night before he came in he had to get up fifteen times to pass his urine. At time of admission he was unable to urinate and had to be catheterized.

Previous History.—Had gonorrhea twenty years ago, followed by gleet. Last winter was troubled with frequent urinations. He had one attack of retention one year ago.

Examination.—Bladder enormously distended. Prostate greatly enlarged. Examination of urine: amber, normal odor, acid reaction; sp. gravity, 1020; no albumin, no sugar; few red blood corpuscles.

Operation.—Aug. 26, 1902: Regular technic. Permanent catheter inserted. Left hospital Nov. 7, 1902, with perineal wound closed. Urinated a large amount every two hours without pain. Control was good, though after micturition there was some dribbling for a few minutes. Patient has not been heard from since.

CASE 20.—Mr. J. B., aged 60 years. Occupation, watchman. Entered Cook County Hospital Sept. 20, 1902.

Present Illness.—Since September, 1901, patient has suffered from frequent urination. Has been catheterized twice daily since entering the hospital.

Examination.—Bladder distended above symphysis. Prostate markedly enlarged. Urinary examination: yellow, pale, 1013; albumin present; no sugar; moderate number of hyaline and granular casts; few pus cells.

Operation.—Sept. 26, 1902: Regular technic. Patient discharged from hospital Jan. 13, 1903, with perineal wound closed. April 2, 1903: Wound has opened periodically since he left the hospital, discharging a little urine for a few days and then closing. No discharge from perineum for past week. Excellent control of urine and holds it from two to four hours during day and from two to three hours at night. No pain. Sexual function abolished. Impossible to trace patient since last report.

CASE 21.—Mr. F. D., aged 68 years. Occupation, farmer. Admitted to Mercy Hospital Sept. 26, 1902. Family history negative. Personal history: No serious illnesses.

Present Illness.—Began fifteen years ago with frequent urination. For the last five years he has used catheter daily; of late seven or eight times during the day and six at night.

Examination.—Moderate prostatic enlargement. The distended bladder can be palpated bimanually. A Thompson searcher was passed into the bladder and a large stone found. Examination of urine: yellow, turbid, fetid odor; alkalin reaction; large amount albumin. Microscopic examination shows large number of bacteria present, also pus cells.

Operation.—Sept. 29, 1902: Regular technic. Stone removed. Permanent catheter inserted. Patient was discharged from hospital Oct. 24, 1902, with perineal wound entirely closed and urinary control good.

February, 1903: Wound is entirely healed and he has complete control of the urine. He holds urine three or four hours during the day and six or seven hours during the night. Has no pain. Sexual function is abolished.

Report March 29, 1904: Since last report a calculus has re-formed in the bladder and he is suffering from symptoms caused by this at the present time. Wound has remained healed and urinary control is good, but the stone causes painful and frequent urination. Suprapubic cystotomy was performed, April 16, 1904, and an enormous phosphatic stone removed. Patient is now in the hospital and the wound has not quite healed.

CASE 22.—Mr. P. D., aged 49 years. Occupation, laborer. Admitted to Mercy Hospital Nov. 6, 1902.

Present Illness.—For past four years has noticed increasing difficulty in urination. He has frequent desire to empty bladder and suffers great pain from the tension. Voids urine three to five times during day and from five to seven times at night. Has never used catheter.

Examination.—Prostate considerably enlarged. No stone found. Urinary examination: sp. gravity, 1030; yellow; no albumin; no sugar; no pus or blood.

Operation.—Nov. 10, 1902: Regular technic. Patient discharged from hospital Dec. 10, with perineal wound practically healed and with good control of urine.

Report March 29, 1904: Wound has remained permanently closed. Has only slight occasional pains in bladder just before passing urine. During the day urinates four times and usually does not have to get up at all during the night. Control of urine is perfect. Has not used catheter since operation. Sexual function not impaired. General health excellent.

CASE 23.—Mr. J. W., aged 71 years. Admitted to Mercy Hospital Jan. 4, 1903.

Present Illness.—For past eighteen years patient has suffered from frequent urination, especially at night. Has had to get up three or four times to evacuate the bladder during the night. For the past three months the difficulty in passing his urine has increased. Three months ago had to be catheterized twice daily for eight days.

Examination.—Arteries sclerotic. Prostate considerably enlarged. Examination of urine: 1680 c.c. in twenty-four hours; yellow; turbid; albumin present; no casts; large amount of pus.

Operation.—Jan. 7, 1903: Regular technic. Patient did well after the operation and was out of bed in wheel chair January 16. January 17 he developed symptoms of cerebral embolism, which continued until January 25, when he died.

CASE 24.—Mr. A. B., aged 63 years. Occupation, farmer. Admitted to Mercy Hospital Jan. 10, 1903.

Present Illness.—Began three years ago with increased frequency of urination, every two to three hours. Since eighteen months ago he has catheterized himself every three hours.

Examination.—Prostate considerably enlarged. Urinalysis: yellow, acid, trace of albumin, no sugar, pus cells abundant, no casts.

Operation.—Jan. 12, 1903: Regular technic. Patient discharged from hospital Feb. 11, 1903, with perineal wound closed and good control of bladder.

Report March 29, 1904: Wound has remained permanently closed. No pain, but some slight tenderness in perineum. Holds urine during the day two hours or longer and at night from one and a half to two hours. Control of urine excellent. Has not used catheter since operation. Sexual function lost. General health excellent.

(To be continued.)

NOTE.—The continuation of the paper of Drs. Jackson, Porter and Quinby, begun in last issue, is unavoidably postponed.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

SATURDAY, JUNE 11, 1904.

THE PRESIDENT'S ADDRESS, AND THE ANNUAL ORATIONS.

The addresses published in this issue call for special notice for many reasons. The President's address is a review of the Association's problems and its work. He finds much reason for congratulation; the progress that has been made in organization has been most striking and the prospects for future enlargement and for the unification of the profession are most bright. The Section work of the Association is one of the most important objects of the annual session, and his suggestions regarding it are worthy of consideration. The suggestion that the sections organize special international congresses when the time is ripe will, we trust, be a fruitful one Dr. Musser's remarks on sanitary science and its advance, and the position of the profession toward the public in this particular, are timely, and we hope will receive the attention they merit. But that portion of the address bearing on medical education especially calls for notice here. The history of the Association has been wrapped up in this subject to a greater or less extent, but it is only of late years that we are appreciating the fact that in our zeal for higher education we have been multiplying the facilities beyond the demand, and encouraging many who are not fitted for practice to take the easiest route into the ranks. The value of a general liberal education to the physician is also a point which is very properly emphasized in the address, and the tendency of Dr. Musser's thought is toward the final requirement of a still higher standard of general education as a preliminary to entrance into medical professional studies. He thinks that there should be one educational requirement, the equivalent of that for which a first-class college degree stands, and the necessity of the hospital year as the finish of the culture required by an individual who is to go forth as a physician, is one that can not be too strongly emphasized. At the present it may be an ideal which we can not altogether live up to, but if we hold it strongly as an ideal we will more constantly approach it, and the time will probably come, perhaps not so far ahead, when no man will be considered as fitted to go out into the world to care for the health and welfare of his fellows who has not had at least a year's practical, thorough training under the leaders of the profession in the hospitals of his country. The public also needs education in this regard; but we do not think that that will be a difficult problem. The fact that hospitals give to nurses the highest opportunities, and yet have not always given them to the embryo physician, who has to be above them, is altogether an irrational condition of affairs. There are other points in Dr. Musser's address that call for mention, but space forbids.

The Oration on Medicine by Dr. Dock takes up a subject that is rarely treated of on such occasions, and, therefore, has the merit of novelty in addition to its own intrinsic merits. It raises some interesting ethical questions. The matter of prognosis is a practical one to the practicing physician, and no one knows at what time he may be called on to exercise his best judgment in this direction. Dr. Dock treats the subject most interestingly and the address is full of thought. Personally, we do not believe that actual falsehood is ever required. While there is life there is hope, even though that hope may be infinitesimal, and we think that a guarded statement of the possibilities, given, however, with a hopeful and cheerful accompaniment, is always far better than a misstatement. The patient's welfare should always be before us, and it is no satisfaction to know that the patient passes away under a false impression raised by his physician. There is plenty of room for individualization in this matter, and, as we understand it, Dr. Dock takes a similar view to that expressed above.

There are probably few American surgeons who are better qualified to give the Oration on Surgery than Dr. Mayo. He takes up a comparatively limited subject—surgical diseases of the upper abdomen—but it is treated with the thoroughness that might be expected from his ample experience. The upper abdomen has been one of the recent conquests of surgery, and the progress that has been made is well shown in his address. Conditions which formerly were hopeless have been rid of nearly all their terrors owing to the advances of the past few years, and the prospect for still better work in the future is most hopeful.

The Oration on State Medicine by Dr. Biggs points out with justice what has been done in the line of preventive medicine, facts that have not been appreciated by the profession or the public. It is not alone in such obvious matters as vaccination and antitoxin that the advances are seen. The hosts of disease, as we are learning to appreciate, are coming more and more under human command. Dr. Biggs is an advocate of the extension of notification of disease to a large class of disorders that now escape, and his remarks on this point deserve attention. There is little doubt that, when we understand the dangers, public opinion will support notification, and that, even in such conditions as typhoid fever, pneumonia and tuberculosis, with due precautions by thoroughly intelligent health officers, it need not add to the inconvenience of the sufferers, but will greatly aid in the security of their fellows. There are still problems for sanitation to meet, as is shown by the increasing mortality from respiratory diseases of late years, yet the fact is that the gains that we have made make the future most promising.

SOURCES OF INFECTION IN TYPHOID FEVER.

The opinions recently expressed by Koch on the modes of infection in typhoid fever are being made the basis of action in several parts of the German Empire, and the various inquiries that have been set on foot at Koch's instigation seem likely to shed light on some of the obscurer problems relating to the dissemination of typhoid fever among both urban and rural communities.

One of the most recent studies of this character is by Dönitz,[1] and treats of an investigation into the origin of the 122 cases of typhoid fever that were reported in Berlin between Oct. 20, 1902, and June 30, 1903. Eighteen of this number were rejected on the ground of questionable or mistaken diagnosis, and 21 were excluded as being imported cases. Of the remaining 83, 37 could be ascribed to definite causes, namely, 18 to contact infection, 6 to water infection (bathing), 3 to infection on the sewage farms, and 10 to milk. The remaining cases, for varying reasons, could not be traced with any reasonable degree of certainty. Dönitz, however, enumerates other possible sources of infection which may conceivably have been responsible for the causation of the untraced cases, such as the use of raw vegetables or of infected butter. He considers briefly the possibility of housefly infection, but does not attribute much importance to this mode of dissemination under present Berlin conditions; he also dwells on the possibility of rat transmission, which he seems to regard as a factor worthy of investigation. Some readers may deem it curious that the possibility of oyster infection, which has recently excited so much interest among English and American sanitarians, is not mentioned.

The underlying principle of the present campaign against typhoid fever in Germany, of which such painstaking researches as that by Dönitz form an important feature, seems to have been misunderstood in some quarters. The movement to eradicate typhoid fever by exercising a more rigorous control over the opportunities for contact infection, and the other modes of spread above mentioned, has been taken as indicating that drinking water infection is either less common than has been generally supposed, or is of distinctly subordinate importance. No assumption could be more wide of the mark. The truth is that in Germany drinking water infection has been reduced to a minimum by government supervision and regulation of public water supplies, and that such scattered cases of typhoid fever as now occur in the large cities are due to other causes. This condition, however, affords no ground for setting aside the evidence of the frequency and importance of water infection in those countries where the water supplies are less carefully guarded. No one at all cognizant of the character and mass of this evidence can entertain a doubt that the excessive prevalence of typhoid fever in the United States is directly attributable to contaminated water supplies. It is not necessary to shut our eyes to the greater danger in order to appreciate the existence of the lesser.

It will be generally admitted, however, that in our zeal to remedy the deplorable conditions surrounding many of our public water supplies in this country we have as yet paid insufficient attention to those less conspicuous modes of dissemination against which the German sanitariums are now beginning their campaign of extermination. In spite of the costly experience gained in the military camps during the Spanish-American war, the prevention of contact infection has not been given the serious consideration it deserves.

DECAPSULATION OF THE KIDNEY FROM THE EXPERIMENTAL STANDPOINT.

Since decapsulation of the kidney was first proposed as a therapeutic procedure explanations as to the rationale of the results have not been lacking. Inasmuch as autopsies on these cases have so far been very infrequent, the writers of the earlier articles relied for their theories on analogy or pure supposition. Within the last six months a number of articles have appeared dealing with the subject from an experimental point of view. In this country, Harold Johnson,[1] and in Germany, Asakura and Stursberg,[2] have studied the effect of decapsulation on normal kidneys by the experimental method.

In a recent article Hall and Herxheimer[3] publish the results of their work on normal kidneys, and also on kidneys in which an acute nephritis had been experimentally produced. The results of decapsulation of normal kidneys were the same as those observed by Johnson; at the end of from ten days to three weeks a new capsule, in many cases thicker than the original one, had formed. Furthermore, neither Johnson nor Hall and Herxheimer were able to find any evidence of increased vascular connection between the new-formed capsule and the cortex of the kidney. In producing an experimental nephritis Hall and Herxheimer used ammonium chromate, which produced a degenerative nephritis with albumin and casts in the urine lasting from sixteen to eighteen days if the animal survived. The decapsulation was sometimes unilateral and sometimes bilateral, and was usually performed on the third day. A naked eye examination of these kidneys showed that, as a rule, a new capsule as thick as the old one had formed by the end of ten days; if the animal was permitted to live longer than this, the capsule became thicker than normal and often became adherent to surrounding organs. Microscopic examination showed that the new capsule was fibrous in character and often dipped down into the kidney where the organ had been injured by the decapsulation, so that the appearance of early interstitial nephritis was produced in some instances.

The authors conclude from their work that from an anatomic standpoint there is no very satisfactory explanation of the effects of decapsulation; there is no evidence that the decapsulation produces improved circulation, at any rate in acute cases, and in some cases an actual increase in the connective tissue of the organ was produced. They point out that the effect of decapsulation on chronic nephritis has so far escaped experimental study, as we know of no way of producing chronic nephritis in animals. From analogy to the effects produced in acute cases, however, it seems unlikely that a satisfactory anatomic explanation will be found. The failure to show that the good effects of the decapsulation are due to increased circulation, or to the relief of tension, which did not occur in some of their experimental cases, leads the authors to suggest that a reflex action on the sympathetic may cause the improvement. If this is the case, they argue that the so-called reni-puncture, i. e., the mere splitting of the capsule by longitudinal and transverse incisions, should be just as effective as, and much less dangerous than, decapsulation.

TRAUMATIC ASPHYXIA.

Occasionally, as a result of forcible compression of the chest for a varying period of time, with entire cessation of respiration, there occurs a condition that has been designated traumatic asphyxia or apnea. This is characterized by a discoloration confined, as a rule, to the face and the neck above the clavicles, varying from red through blue to black, and not disappearing on pressure. Some of the lesions present a petechial appearance, while others are more distinctly hemorrhagic. Subconjunctival ecchymoses likewise occur at times, and vision may be impaired. The discoloration has been attributed to extravasation of blood of varying amount as a result of compression of the thorax, without, necessarily, injury to the head itself. The increased intrathoracic pressure is transmitted to the veins of the head and the neck, to which it is limited in consequence of the absence of functionating valves.

Only a few cases of the kind in which recovery has taken place have been recorded in the literature, and an additional one has recently been put on record by Dr. H. H. A. Beach and Dr. Farrar Cobb,[1] together with a description of the minute pathology, as determined by microscopic examination of sections of the skin taken from the patient. The latter was a man, 30 years old, who had been caught and held by a moving freight-elevator, and was released in from three to five minutes. His face became black, blood escaped from his mouth and nose, and his eyes protruded. He was unconscious for a few minutes. When examined, an hour later, the man was in a state of moderate shock, with a temperature of 99.5, perfectly conscious, but dull and sluggish. The skin of the abdomen was the seat of several contusions, and a large fluctuating hematoma was present in the left loin and back, low down, toward the pelvis. The eighth and ninth ribs on the left side were fractured in the midaxillary line, and there was a moderate amount of subcutaneous emphysema for a short distance in this vicinity. The skin of the face seemed to be dotted with countless spots, from black and reddish-black to blue in color, close together, with minute intervening lines or areas of apparently normal skin. The discoloration was limited below, anteriorly, by a transverse line passing through the inner extremities of the clavicles, while posteriorly it occupied the double triangles formed by the trapezius muscles. No retinal hemorrhage was found on ophthalmoscopic examination. Extensive hemorrhage had taken place beneath the conjunctivæ. The pupils were equal and reactive to light. The urine exhibited no abnormality. On the third day the temperature rose to 106, the breathing became labored, there was slight bloody expectoration, and many râles were audible; but these conditions disappeared in the course of twenty-four hours. The hematoma on the back was aspirated six times, from one to two pints of bloody serum being withdrawn each time. The fluid, however, reaccumulated rapidly, so that, finally, a free incision and packing with gauze became necessary. On the second day, while the discoloration still exhibited its greatest intensity, pieces of skin from the affected parts were removed for histologic study. The discoloration disappeared rapidly after the third day, simply fading away and changing from a black to a leaden color and becoming cloudy, the face presenting only a suffused appearance at the end of three weeks. The subconjunctival extravasations underwent the usual changes. Microscopic examination of sections of the skin excised showed the tissues to be entirely normal and free from extravasated blood.

The practical deduction from this observation is the institution of artificial respiration, in conjunction with inhalation of oxygen, immediately after the release of an individual who has been subjected to forcible compression and presents livid or cyanotic discoloration of the face and neck.

HEALTH OF ITALIAN IMMIGRANTS.

Charities has recently published the first of a series of studies on the foreign elements in our country. The series begins with Italians, an important class of immigrants, both on account of their number (there are said to be 382,000 in New York City alone) and because they are, for obvious reasons, not as well understood by the ordinary American as immigrants from Northern Europe.

The publication consists of a number of articles by American and Italian-American social workers and physicians, and it is those by the latter, dealing, as they do, with disease among the Italian immigrants, which are of special interest to us. Dr. Rocco Brindisi of Boston takes up the question of the Italian and public health; Dr. Antonio Stella of New York, the question of tuberculosis among the Italians.

When he enters this country the Italian is usually strong and healthy, the old and feeble are mostly excluded by our immigration laws. He is likely to be a sturdy peasant from the Southern Apennines, from Calabria, Basilicato, Abruzzi, or from Sicily, accustomed to an out-of-door life, inured to hard labor, temperate in his habits. Unfortunately, the change to this country is a severe strain on his naturally robust constitution, and, although the mortality remains low among the Italian men, the morbidity is far greater than in Italy. The severe climate is apt to cause rheumatism, bronchitis and pneumonia, and the sudden change from a vegetarian to a meat diet makes stomach troubles. As is always true of a foreign colony in which there is a great preponderance of males. venereal disease is quite frequent. The death rate from venereal disease among persons under 45 years of age in the registration area of the United States in 1900 was higher for the Italians than for any other white element. but, according to Dr. Brindisi, this is not true of the present time, owing to the increasing tendency of the men to send home for their families, and the consequent raising of the moral tone of the community. The great advantage of the Italian in his struggle with disease is his temperance as regards alcoholic drinks. Alcoholism is practically unknown among the newly immigrated. but it is a mortifying fact that almost the first lesson taught them in America is the substitution of beer and whiskey for their harmless light wines.

---

[1] Annals of Surgery, April, 1904, p. 481. See The Journal, May 7, 1904, p. 1232, ¶32.

The woman suffers more than the man from the sudden change to this country. Accustomed to spend almost all her time in the open air, she now finds herself shut up in a crowded, insanitary tenement, and, instead of working in the fields and vineyards, she "finishes" coats and trousers for the sweaters. A too-productive maternity and a prolonged lactation add their share to the undermining of her health. The mortality among women is greater than that among men, and the mortality among children, especially the American born, is much greater. Rickets is quite common among these children; tuberculosis, acute respiratory disease and acute intestinal disease carry off many of them in early infancy. Those who live to grow up are apt to be frail and undersized, in contrast to their sturdier parents.

Dr. Stella maintains that tuberculosis is common, in spite of the low mortality record from this disease, this latter being due to the tendency on the part of Italians who are stricken with tuberculosis to go home to die. His theory is apparently borne out by the statistics of the New York Health Department, which show that the Italians stand only tenth in the list of the nationalities as far as deaths from this disease between the ages of 15 and 45 are concerned, but they come second in the list for mortality below the fifteenth year—children being generally not sent back to Italy to die. Tuberculosis among the Italians is pre-eminently a house disease. Dr. Stella speaks of houses in New York which yielded twenty-five to thirty cases each in the course of a year. and this from among a people who, in their own country are exceptionally free from tuberculosis.

This brings us to the conclusion, inevitably, although not expressedly, drawn in the publication in question. namely, that the Italian within our gates is far more sinned against than sinning. He comes to this country largely because he is induced thereto by the golden promises of steamship immigration agents, and when here he undertakes heavy manual labor or insanitary rag-picking, cigar-making, and sweat-shop work. He lives in insanitary, crowded tenements, sunless, one might almost say airless, and often filthy, because his wages will not permit him to get better ones. Moreover, in his own country his house has always been a negligible quantity, life being spent in the fields or on the "piazza" of the town, so that he is not accustomed to fastidiousness in this respect. The filthiness of Italian tenements in this country is certainly not entirely chargeable to the tenants. According to a tenement house inspector in Philadelphia, the rooms in the tenements were often far cleaner than the halls, alleys and courts, for which the landlord is responsible. Insufficient water supply, defective drainage, dark rooms and overcrowding are conditions against which the Italian tenant is powerless. It is probable that New York, Boston and Chicago are almost as blamable in these respects as Philadelphia.

The solution for the problem of Italian immigration lies, according to these authorities, in devising means to distribute it throughout the agricultural regions of our country and to prevent congestion in cities. Agricultural colonies are already in successful operation in six states, and in them the Italian peasant finds the work. surroundings, and, to a great extent, the climatic conditions to which he is accustomed. Certainly this seems more promising than any other suggestion which has been made for the betterment of this class of immigrants.

THE CANDY THAT WE EAT.

Under the above heading is printed, in the June number of the *Ladies' Home Journal*, a well-meaning editorial directed against the filthy custom of the cheaper shops of exposing sticky candy to contamination with all sorts of floating dust and dirt. Unquestionably this practice is to be decried, and the purchase of such articles discouraged; but, unfortunately, a rather remarkable statement is made in explaining the danger of such candy. "A prominent physician, whose word is equivalent to that of highest authority," is credited with the following startling observation: Examining some of the questionable candy with his microscope, he found that "there were typhoid and malarial germs absolutely without number—the candy was literally covered with them." The discovery of and recognition of malarial germs on a foreign body is a new contribution to the habitat of the pesky protozoa, and the technic involved must be a distinct addition to any yet known to ordinary microscopists. Are we to understand that the "malarial germs" pass part of their existence in the street dirt, or did a cloud of anopheles swarm down on the exposed candy and deposit their obnoxious lodgers in its sticky sweetness? And were the malarial germs in the form of adults, of microgametocytes, or sporozoites, or what? General interest would also be awakened by a demonstration of the peculiar morphologic characteristics developed by the typhoid bacillus, when it grows on candy, which make it so easily distinguished from the colon and other members of the group. We fear someone has been joking with Mr. Bok.

TROPICAL TROOPS IN HIGH ALTITUDES.

Perhaps one of the most interesting military expeditions from a sanitary point of view is that now being conducted by the British in their advance on the capital of Thibet. Some of the passes traversed are said to be three miles above the sea level, and it is a well-known fact that a large part of the campaign must be conducted on a plateau thousands of feet above the level of the sea. The fact that Indian troops from a tropical country are employed on this expedition, as well as Europeans, is also of interest. Hitherto, so far as the dispatches inform us, the men have not been seriously affected by the altitude, but it will be of interest to have a medical report of the results of the expedition on the physique and the health of its members. The force is not a large one, but sufficient to furnish valuable information if the facts are properly collected and collated. We trust that there are medical men connected with the expedition who are competent to make this report, and that we may have an addition to our knowledge of human endurance and sanitary science.

BOVINE AND HUMAN TUBERCULOSIS.

News comes by cable from London that the royal commission appointed nearly three years ago to investigate the connection between human and animal tuberculosis and to test the correctness of Koch's uttered opinions has reached certain conclusions that it feels justified in giving to the public, and which, in fact, refute the claim of the distinguished German bacteriologist. They say, according to the report: "We have most carefully compared the tuberculosis set up in bovine animals by material of human tuberculosis, to that set up in bovine animals by material of bovine origin, and so far we have found the one, both in its broad general effects and in its finer histologic details, identical with the other." According to the judgment of the commission, therefore, it would be unwise to modify legislative measures on the presumption that human and bovine tuberculous bacilli are specifically different or that the disease caused by the one is different from that due to the other. This is not the final official report, which will give detailed particulars, but so far as it goes may be depended on.

A DISREGARDED SOURCE OF SURGICAL INFECTIONS.

It has long been recognized that saliva is an extremely dangerous medium of infection, but it has remained for de Leon[1] to demonstrate just how frequently it may be responsible for the instances of so-called unavoidable surgical infection. From a long series of careful and well-controlled experiments, he has obtained some very striking results. It was found that on the average about two hundred words were spoken by the operator alone in an ordinary operation. On an average, in each drop of saliva occur 4,375 bacteria, and in the duration of an average operation 250,000 organisms may gain direct entrance to the wound. Among these, virulent organisms are constantly present, streptococci, diplococci and staphylococci, in order of their frequency. To avoid this source of contamination, de Leon devised a simple mouth mask which is efficacious and not burdensome and does not interfere with distinct articulation. Some bacteria were found to penetrate a gauze mouth covering, though the number was materially reduced. If experience has shown that wounds are usually capable of withstanding a large number of bacteria, it has also demonstrated that under suitable conditions a few bacteria may give rise to serious and even fatal infection. Inasmuch as these conditions may obtain in any wound, the logical deduction is obvious. It would be folly, indeed, to strain at the gnat of saliva and swallow the camel of dirty hands, but surgeons who have good personal technic and equally careful assistants should consider this fruitful source of infection, particularly where teaching makes more continuous and louder talking a necessity. (See page 1523.)

LODGE PRACTICE AND THE WELL-TO-DO.

An interesting little social fact is remarked on editorially by the *Australasian Medical Gazette,* April 20. Australia is a lodge-ridden country to all appearances, and the medical profession is more or less sweated, to use the usual term; in fact, probably more so than most other countries, though the fees may not be so ridiculously small as those against which our German confrères have successfully rebelled. The *Gazette* remarks that it may be interesting to its readers as well as to the general public to know that the complaints that have been made from time to time in regard to sweating the profession by the well-to-do are not without foundation. It says it has been informed, on good authority, that one of the members of the federal ministry of Australia, whose wife is a wealthy woman, takes advantage of his membership in a friendly lodge to procure medical treatment for himself and family. This is not, it says, the first and only occasion in which a cabinet minister has availed himself of the services of a lodge doctor, but it suggests that one would think a federal minister would have had more self-respect and dignity than to get medical attendance in such a cheap way, because he happened to be a member of a friendly society. In this country we are somewhat accustomed to the fact that dispensary practice in large cities is utilized by a considerable number of well-to-do individuals. It is not an unknown experience for a dispensary physician to see his patients decked out in silks and diamonds or to find that they are extensive landlords and recipients of presumably large incomes. The remedy here, however, is patent; when the facts are known, the services are discontinued; but in a country where lodge practice is almost the rule, the public seems to lose self-respect and only endeavors to obtain the services of physicians at the cheapest possible rate. We mention this fact as something that we may possibly yet experience. Fortunately, we have not yet seen the Secretary of the Treasury, or of State, or any other cabinet minister, utilizing lodge membership for his medical attendance.

---

Medical News.

DISTRICT OF COLUMBIA.

Health of the District.—The report of the health officer for the week ended May 28 shows the total number of deaths to have been 102. At the close of the report there were under treatment 9 cases of diphtheria, 21 of scarlet fever, 39 of typhoid fever and 5 of smallpox.

New Hospital.—The new home of the Episcopal Eye, Ear and Throat Hospital, Washington, was dedicated June 4 with appropriate ceremonies. The building, when complete, will have cost about $100,000. It is completely fire-proof, and is equipped with elevator and will accommodate 16 private patients and 35 ward patients, exclusive of the quarters for the resident physician and superintendent of nurses. It has separate wards for colored and white patients.

Health and Quarantine Conference.—The second annual conference of state health and quarantine officers, with the U. S. Public Health and Marine-Hospital Service, met June 3 and 4 in Washington. The president, Surgeon-General Walter Wyman, announced that there were no problems of pressing importance from a national point of view for him to present to the conference. He gave a résumé of the year's work in detail, and announced the formation of two new divisions in his department, one on zoology and one on pharmacology, and also that the Mexican authorities had agreed to co-operate with the United States in the suppression of yellow fever. The following officers were elected: President, Dr. John S. Fulton, Baltimore; vice-president, Dr. N. K. Foster, San Francisco; treasurer, Dr. James A. Egan, Springfield, Ill., and secretary, Dr. Gardiner T. Swarts, Providence, R. I.

Nostrum Fraud Order.—The postmaster general, in reply to a criticism of a lay newspaper, has given out a statement regarding the attitude of the department toward worthless nostrums and newspaper publication of obscene advertisements. He states that the department has no intention of entering on a crusade against patent medicines nor of establishing a censorship on advertisements printed in newspapers, but simply intends to correct abuses in case of obscenity and fraud, as by law he is required to do. He says that the analysis of certain so-called remedies developed the fact that in most instances the ingredients were simply starch and sugar. In a number of instances pills and drugs contained ingredients injurious to health and by law forbidden to be sold. As it appeared that certain companies were defrauding the public by means of false representations, made through the medium of the mails, the issuance of fraud order was recommended to the postmaster general and issued by him. He says the department intends to act promptly with all concerns dealing in the remedies described, though this can be brought about only through complaints received from victims and from the publication of advertisements which, in the judgment of the department, are in violation of the statute against obscenity. In the latter case, newspapers publishing such advertisements will in time come under the ban of the law, for as the advertisements are not admissible to the mails, the papers printing them must be included in the same category. The latter will have to cease printing the objectionable advertisements or will have to be refused transmission through the mails.

ILLINOIS.

Personal.—Dr. John W. Cantrell, Rochester, suffered a sprain of the ankle and severe cuts and bruises in a runaway accident May 27.——Dr. Jas. T. Crow, Carrollton, was recently adjudged insane and committed to the Illinois Central Hospital for the Insane, Jacksonville.

Tuberculosis Camp.—A camp which will accommodate 30 poor tuberculous patients was recently opened near Ottawa under the auspices of the Illinois State Medical Society. It will be in charge of Dr. James W. Pettit of Ottawa, and is expected to be virtually self-supporting.

New Hospitals Favored.—The board of commissioners of Cook County is considering the question of hospital accommodation in districts remote from the county institution. The proposition calls for the following:

An emergency hospital in the down-town district.

A centrally located hospital in the manufacturing district in the extreme southern part of the city.

A hospital conveniently located for the manufacturing district, as well as the stock yards on both sides of the river.

A hospital conveniently located for the manufacturing district in that part of the town.

The proposals were favored by members of the board and referred to the finance committee.

Chicago.

Two Spitters Arrested.—After a long period of quiescence the anti-spitting ordinance was remembered last week, when two men were arrested for expectorating on the sidewalk.

Personal.—Dr. George W. Hall and family have sailed for Europe.——Dr. David F. Monash sails for Europe June 14.——Dr. Charles Davison has been nominated for trustee of the University of Illinois.

May's Deaths.—During May 2,225 deaths occurred, equivalent to an annual death rate of 13.6. This is nearly 13 per cent. lower than the average mortality for May, and nearly 20 per cent. less than the mortality for May, 1903.

Neck and Neck.—The week ended June 4 is the first time since last October that the weekly pneumonia deaths have not exceeded the deaths from consumption. The 67 deaths from each cause represent 14.8 per cent. of the total mortality, instead of, as heretofore, 10.7 per cent. for consumption and 22 per cent. for pneumonia.

INDIAN TERRITORY.

Medical Bill Passed.—Congress has passed the bill regulating the practice of medicine in the Indian Territory. It provides for a medical examining board in each district composed of three physicians appointed by the district judge.

Examining Boards Appointed.—Drs. Benjamin F. Fortner, Vinita, Jesse C. Bushyhead, Claremore, and William L. McWilliams, Miami, have been appointed members of the territorial medical board for the northern district.——For the Chickasaw Nation, the following have been designated as the medical examining board: Drs. Jerome C. McNees, Ardmore, E. E. Chivers, Mannsville, and William L. Peters, Chickasha.——The new medical examining board for the Choctaw Nation is composed of Drs. Alfred Griffith, South McAlester, J. B. Smith, Durant, and B. W. Caldwell, Hugo.

South McAlester's Hospitals.—South McAlester, a city of 10,000 inhabitants has two hospitals, All Saints' and Sisters of Mercy. The former has a very efficient training school for nurses. The latter has recently opened a bacteriologic and pathologic laboratory and an outdoor clinic, with the following staff: General medicine, Drs. Alfred Griffith, and J. E. Little; diseases of women, Dr. William B. Pigg; diseases of children, Dr. Thomas S. Chapman; genitourinary diseases, Dr. H. Earle Williams; diseases of rectum, Dr. Rufus Crabill; dermatology, Drs. Robert A. Munn and McClellan Wilson, and surgery, Dr. Troy.

Chickasaw Medical Association.—The ninth semi-annual meeting of the association was held in Ardmore, May 10 and 11. The attendance was the best in the history of the organization, and there were 23 applications for membership. The officers elected were as follows: President, Dr. John D. Batson, Marietta; vice-president, Dr. Risdon D. Moore, Ardmore; secretary-treasurer, Dr. Joseph W. Shelton, Wynnewood; delegates to the Indian Territory Medical Association, Drs. James W. Gilbert, Roff, and Joseph W. Shelton, Wynnewood; alternate, Dr. Herbert P. Wilson, Wynnewood, and censors, Drs. Thomas S. Booth, Ardmore, three years, James F. Roberson, Duncan, two years, and John R. Runyan, Ada, one year. Pauls Valley was chosen for the next meeting place.

MARYLAND.

Baltimore.

May Health Report.—During May, 869 deaths were reported. Measles, scarlet fever and smallpox were prevalent, 108 cases of the first, 192 of the second, and 20 cases of the third being reported to the health department.

Free Baths Open.—The Free Public Bath Commission announces that the summer bathing pools and women's baths are open for the season. The Walters Public Baths, which are open the whole year, have had more than 21,000 patrons in the last two weeks.

Personal.—Dr. Charles E. Simon has gone to Chester, Nova Scotia, for the summer.——Dr. Champe S. Bradfote disappeared from his home here May 11. He was a native of Texas, and for some time connected with the teaching staff of Jefferson Medical College.——Dr. H. M. Cohen sailed for Europe May 20.

Vaccine Physicians Appointed.—The following have been appointed extra vaccine physicians: Drs. Hugo Weusthoff, Melchija Spragins, Frank O. Miller, R. Perry Carman, Joseph H. Brewster, W. De F. Olmstead, W. K. White, Christian Waldkoenig, J. Charles Beck, John C. Travers, Isham R. Page, Edgar M. Parlett, Samuel Weinberg, J. D. Quinn, W. H. Clendinen Teal, Howard E. Wooden, Edward W. Gilliam, J. H. Jenkins, W. L. Nicholls, Martin A. O'Neill, William H. Pearce, Fred C. Jewett, Jay H. Iglehart, Thomas L. Savin, and Daniel W. Smith.

MASSACHUSETTS.

Personal.—Dr. William A. Brooks, Jr., Boston, recently sailed for a two months' trip in Europe.

Transportation of Contagious Cases.—A bill has been signed by the governor perfecting the present law so that the State Board of Charity may remove from one place to another a person suffering from a contagious disease. This legislation was made necessary by reason of a case of leprosy recently discovered in the Cape Cod section.

New Hospital in Brookline.—The new private hospital on Corey Hill, Brookline, was opened June 2. The hospital has been constructed after the most approved plans and has 35 beds. Among the Boston physicians who have official connection with the institution are: Drs. Maurice H. Richardson, Charles B. Porter, Joel E. Goldthwait, James G. Mumford, Franz Pfaff, Elliott G. Brackett and William A. Brooks, Jr.

More Anthrax in Lynn.—Another case of anthrax has appeared in Lynn. The victim was not a leather worker, but a wealthy coal dealer. The point of infection was at the angle of the jaw, and owing to prompt surgical interference, recovery seems assured. The source of infection is entirely a matter of conjecture. There have been 18 cases of anthrax in Lynn during the past three years; 3 cases, with 2 deaths, within three months. This latest case has aroused the board of health to energetic action, and with the co-operation of specialists, stringent measures are likely to be adopted, both as regards prophylaxis and the isolation of any case that may occur.

NEW YORK.

To Care for Advanced Consumptives.—The Reception Hospital has been incorporated to maintain a hospital in North Elba, Saranac Lake village, which is intended to relieve a class of sufferers who are turned away everywhere else because their cases are too far advanced. Drs. E. L. Trudeau and Edward R. Baldwin are on the board of managers.

Transfers in State Hospitals.—At a meeting of the State Commission in Lunacy the following transfers of superintendents were ordered to take place June 1: Dr. O. M. Dewing, from the Long Island State Hospital, King's Park, to the Long Island State Hospital, Flatbush; Dr. W. A. Macy, from the Willard State Hospital to the Long Island State Hospital, King's Park, and Dr. R. M. Elliott, from the Long Island State Hospital, Flatbush, to the Willard State Hospital.

Criminal and Insane Aliens.—The Department of Commerce and Labor is compiling an accurate list of all alien inmates of institutions maintained by charity. This list for the city and state of New York has been completed and shows that the number of aliens of all classes supported in public institutions of this state is 13,143. The penal institutions of New York City contain 1,090 alien inmates, and in the state there 1,103. The alien insane of New York number 6,148, of whom 4,224 are in New York City alone. Confined in city homes, juvenile asylums, poor-houses and other institutions not shown in the statistics there are 2,991. The hospitals of the city of New York contain 1,105 alien inmates, and those of the state 121 more. This gives a total of 60 per cent. of the insane as aliens.

NEW YORK CITY.

Knopf's Essay Translated in Japanese.—Dr. S. A. Knopf's essay "Tuberculosis as a Disease of the Masses and How to Combat It," received the Berlin Tuberculosis Congress prize in 1899, has now been translated into Japanese by Dr. Goro-Shibayama, with a preface by Professor S. Kitasato.

No Abatement in Meningitis.—With a death-list of 80 from cerebrospinal meningitis, as against 12 for the corresponding week in 1903, there is little or no decrease in this disease. Of the 80, 30 were under five years of age; 26 between the ages of 5 and 15; 17 between 15 and 25, and 7 between 25 and 45.

Personal.—Dr. Spratling will enter on his duties as superintendent of Bellevue and Allied hospitals June 15.——Dr. Thomas F. Reilly was thrown from his runabout May 30, and severely cut and bruised about the head.——Dr. Stephen Cook has been elected president of the Board of Police Surgeons.

Contagious Diseases.—There were reported to the sanitary bureau of this city for the week ended May 28, 1,107 cases of measles, with 32 deaths; 376 cases of diphtheria, with 49 deaths; 312 cases of scarlet fever, with 22 deaths; 1 case of smallpox; 68 cases of varicella; 403 cases of tuberculosis and 158 deaths, and 22 cases of typhoid fever, with 14 deaths.

Sea-Shore Camp for Consumptives.—The fresh-air department of the New York Association for Improving the Condition of the Poor invites applications for admission to its seaside camp at Coney Island for children suffering from tuberculosis of bones and glands. If the experiment proves that the American seashore, like that of France, affords the most favorable opportunity for treating non-pulmonary forms of tuberculosis, the association will endeavor to secure funds for a permanent seaside sanatorium.

Hospital News.—A six-story fire-proof annex is to be added to St. Vincent's Hospital at an estimated cost of $250,000.——Beth Israel Hospital has purchased property adjoining its present site and $3,000 has been added to the building fund during the past week.——The French Benevolent Society transferred the title of the old French Hospital May 31. It has built a new hospital on 34th Street, between 9th and 10th avenues.——Mt. Sinai Hospital has acquired a plot of ground 200 feet by 170 feet; at the northeast corner of 66th Street and Lexington Avenue.

Tuberculosis Among Street Cleaners.—Owing to the reports which have been circulated as to the large number of street cleaners suffering from tuberculosis, the street-cleaning commissioner, Dr. Woodbury, on June 1, began a personal investigation of the physical condition of the 6,000 men in his department, assisted by six physicians from the health board. About 400 men have been examined thus far, and already a number of cases of tuberculosis have been found, but Dr. Woodbury thinks that the percentage will not be by any means as great as has recently been stated. The commissioner proposes to send the more serious cases to the Adirondacks. He could not legally use the city's money for this purpose, but says that he will look after the financial side, and that if the burden is too heavy, his friends will come to his assistance.

PENNSYLVANIA.

Philadelphia.

Bequests.—In disposing of her estate of $172,000 the late Mary J. Mills made bequests to charity as follows: The Home for Incurables, $5,000 for the maintenance of a free bed in the cancer annex of that institution, and Children's Department of the Episcopal Hospital $5,000 for a free bed.

War on Cheap Soda Fountains.—Dairy and Food Commissioner Warren has instituted a campaign against the dispensers of deleterious and impure summer drinks. In the poorer sections of the city a large quantity of summer drinks are used, in which cheap and impure syrups are used. Commissioner Warren's deputy is assigned to work principally in this field.

Rush Monument.—Dr. James C. Wilson, professor of medicine in Jefferson Medical College, has been selected to deliver the eulogy of Rush at the unveiling and dedication of the monument to Benjamin Rush in Washington on June 11. Dr. Wilson's address will appear in The Journal, June 18. Acceptance of the monument as a gift to the nation will be acknowledged by President Roosevelt.

Against Dusty Streets.—As a result of the efforts of the county medical society and the State Society for the Prevention of Tuberculosis, in pointing out dusty streets as a medium in the dissemination of tuberculosis, an appropriation of $4,000 has been made by Council to abate this nuisance by systematic sprinkling. At first only the busy thoroughfares in the central portion of the city will receive attention, but it is hoped that after a time the scope of the work will widen.

Wills Hospital Will Entertain.—The surgical staff of Wills Hospital, Race Street, between Eighteenth and Nineteenth streets, announces a series of special clinics to be held on June 13 and 14, at 2 p. m., to which delegates and members of the association are invited. Prof. A. Maitland Ramsay, M.D., Glasgow, Scotland, will operate. On the evening of June 13, after a meeting of the Wills Hospital Ophthalmic Society, a reception will be tendered Professor Ramsay by the attending surgeons of the hospital, and after the clinic of June 14 the assistant surgeons will be the hosts at a trolley ride and supper at Willow Grove Park

Off for Europe—Dr J William White sailed for Europe May 14——Dr Leonard Pearson of the staff of the Henry Phipps Institute, sailed for Europe May 30, to study particularly the serum treatment of tuberculosis Dr Pearson will begin in England and work through the north of Europe Dr Ravenel, who is already in Europe, will start in Italy and cover the south of Europe The two will meet in Berlin, and finish their work there——Dr Lewis W Steinbach and family sailed for Europe May 10

Health Report—There has been a decrease of more than 50 cases in all forms of contagious disease during the last week, as compared with the previous week, and the deaths from contagious diseases were 29 less than for the week ended May 21 There were only 102 new cases of typhoid reported This is a decrease of 18 for the week The deaths from all causes were 465, a decrease of 29 over the previous week and an increase of 38 over the corresponding period of last year There were 12 deaths from appendicitis, an unusually high number, and 2 deaths from tetanus

Work of Hospitals—The work done in the German Hospital from April 21 to May 26 is given as follows Patients admitted, 310, discharged, 299, deceased, 21, remaining, 182, including 192 present at the beginning of the period In the dispensary 4,308 patients were treated, of whom 830 were new and 186 victims of accidents——At the annual meeting of the trustees of the Jewish Hospital the following report indicating the amount of work done for the year was made. 6,911 patients were treated, 5,517 operations were performed, and 15,876 patients visited the dispensary In the surgical department of the institution the fatalities were less than any year since the hospital was established

GENERAL

American Dermatological Association—At the twenty eighth annual meeting held at Niagara Falls, on June 2 and 3, the following officers were elected President, Dr William T Corlett, Cleveland, vice president, Dr Frank H Montgomery, Chicago, secretary and treasurer, Dr Charles J White, Boston and member of council, Dr John A Fordyce, New York City It was decided to hold the next meeting of the association in New York City, Dec 28, 29 and 30, 1905

American Pediatric Society—At the annual meeting held in Detroit, May 30 and 31 and June 1, the following officers were elected President, Dr Charles G Jennings, Detroit, vice presidents, Drs Charles G Kerley, New York City, and Thompson S Westcott, Philadelphia, secretary, Dr Samuel S Adams, Washington, D C, treasurer, Dr J Park West, Bellaire, Ohio, and recorder and editor, Dr Linnaeus A La Fetra, New York City The 1905 meeting will be held June 19, 20 and 21, at Sagamore Hotel, Lake George

Quarantine Officer for Panama—Admiral Walker, chairman of the Isthmian canal commission, on May 11, requested that Surgeon H R Carter of the Public Health and Marine Hospital Service be ordered to report to the Isthmian Canal Commission for duty on the Isthmus of Panama in connection with quarantine matters there The request has been complied with by the Secretary of the Treasury The selection of Surgeon Carter is a very wise one, as his wide experience as a quarantine officer and sanitarian fits him peculiarly for the problems and responsibilities of quarantine work on the Isthmus——On request of the Department of State, the Panama government on May 21, appointed Assistant Surgeon Claude Pierce, U S P H and M H Service, health officer in charge of the quarantine service at the port of Panama

Quarantine in Panama—Some months ago, in response to a request made by the Panama government, officers of the U S Public Health and Marine Hospital Service stationed at Central and South American ports were instructed to inspect and sign bills of health for vessels bound for ports in Panama, under the United States quarantine regulations, and to treat them as if they were destined for the United States ports In this way that very necessary adjunct of modern quarantine—inspection at ports of departure—was added to the measures already taken to protect the Isthmus The Panama government, however, omitted to issue proper orders to its port authorities prohibiting entry of vessels without these very essential bills of health signed by the Public Health and Marine Hospital Service officers They also failed to inform the steamship companies of the necessity of complying with the new requirement The presence of plague in Callao, Peru, and yellow fever in Guayaquil, Ecuador, and the intimate relations existing between these ports and the Isthmus, caused considerable apprehension among sanitary authorities in view of the lack of adequate quarantine inspection at the port of Panama and the fact that steamships bound for Panama from these infected ports frequently left for Panama without obtaining a bill of health from the Public Health and Marine Hospital Service officer on duty in the United States Consulate Accordingly, representations were made to the Panama government through the State Department that these bills of health should be demanded of vessels on arrival at Panama As a result, the Panama government issued a decree, April 30, by which vessels from ports in which officers of the Public Health and Marine-Hospital Service are stationed must have bills of health viséed by these officers, and informing the steamship companies that in future they must comply with the regulations dictated, or that shall be dictated in the future, by the medical officers of the U S Public Health and Marine Hospital Service in foreign ports

CANADA

Not to Raise Ontario Standard—The medical faculty of Queen's University has decided that it would not be wise to raise the standard of medical matriculation in Ontario, believing that the requirements of the Ontario Medical Council are sufficiently high

Montreal General Hospital Report—During the first quarter of 1904 the Montreal General Hospital treated to a conclusion 754 patients Of this number 69 died, and if the 19 deaths occurring within three days of admission were omitted, the mortality would be 6 6 per cent for the quarter In the outdoor departments there were 9,204 consultations, 244 more than in the corresponding quarter for 1903 Dr McCrae has resigned as resident pathologist and his place has been filled by the appointment of Dr D B Gillies The medical superintendent, Dr W G Turner, will be succeeded June 1 by Dr Roland P Campbell A site has been secured for the new contagious diseases hospital to be erected in connection with this institution It will cost about $150,000, and of this sum only $35,000 has been subscribed

Provincial Consumption Sanitaria—The Canadian Association for the Prevention and Cure of Tuberculosis has appointed a special committee, consisting of Dr P H Bryce (convener), Dr J D Lafferty, Calgary, N W T, Dr C J Fagan, Victoria, B C, Dr Gordon Bell, Winnipeg, its secretary, and a number of laymen, to take steps to secure the co operation of municipalities, provincial governments, and the dominion government, for the establishment of one large sanitarium in each province Another committee was appointed to organize a branch at Ottawa to co operate in the establishment of a sanitarium for Ottawa and the surrounding country The secretary of the association was instructed to deliver lectures through Ontario during June and July and in the maritime provinces during August and September

FOREIGN

International Antituberculosis Congress—Among the resolutions adopted at the International Antituberculosis Congress held at Copenhagen during the last week in May, were those favoring the study of hygiene in schools and universities uniform schedules for tuberculosis statistics, the appointment of a commission to consider the question of the predisposition to tuberculosis, and the enforcement of regulations against expectoration in places of public assemblage Paris was selected as the place for the next congress which will be held in 1905

The New Departure in the History of Sanitation—The questions of proper water supply, drainage and other sanitary measures are generally decided by each town and city for itself, and are too often made political issues This has been especially the case in France, the local political parties generally assuming the advocacy or denunciation of such measures as their platforms, and the taxpayers voting against anything tending to increase the taxes This has all been done away with now. The central government has taken the matter in hand, and made the prefects at the head of the various departments the arbiter in the matter The prefects are administrative officers appointed by the central government, and hence are independent of the local vote The new public health law now in vogue confers on the prefect the power to render sanitary measures obligatory, and to see that they are enforced. his authority backed by the central government One clause in the law provides for the co-operation of several communities to carry out some scheme of sanitation in which all are interested. Another declares that sources of water supply may be condemned and purchased with a protecting zone around them by the local authorities. The power to condemn insanitary dwellings and areas is also conferred on the prefect who is held responsible for the enforcement of the measures decided on by the departmental board of health. The intervention of the prefect is sanctioned only when the local authorities fail to do their duty within a reasonable interval. He is called on to act when the proportion of deaths in a commune during three consecutive years has exceeded that of the country at large, and also in emergencies. Toulon and Havre have long had typhoid fever endemic and cholera frequently epidemic, and yet nothing has been done to remedy the unsanitary conditions that have prevailed there for centuries. The law heralds a new departure in the history of sanitation, making suitable local measures compulsory. The legislators are now debating on the provision for special assessments for these works, apportioning the expense between the commune and the department. The *Lancet* of May 21 gives further details of the new law.

Marriages.

W. H. Taylor, M.D., Manitoba, to Miss Aimee De Vere of Chicago, June 8.

Charles H. Fegers, M.D., to Miss Florence Searles, both of McHenry, Ill., June 8.

Guy Grigsby Dowdall, M.D., to Miss Winifred Warner, both of Clinton, Ill., June 2.

John H. Blackburn, M.D., to Miss Bessie Hatcher, both of Bowling Green, Ky., May 25.

Olline Burton Doyle, M.D., Fresno, Cal., to Miss Ruby H. Perkins of Visalia, Cal., May 10.

Samuel Charles Emley, M.D., Wichita, Kan., to Miss Lalage Hall of Wellington, Kan., June 8.

Abraham H. Faith, M.D., to Miss Nellie Head, both of Washington, Ind., at Indianapolis, May 28.

H. M. Cohen, M.D., Baltimore, to Miss Etta Rothband of Manchester, England, at Manchester, June 8.

Robert W. Hastings, A.M., M.D., Brookline, Mass., to Miss Edith A. Earhart of Hagerstown, Md., June 8.

J. Hester Ward, M.D., Johns, Ala., to Miss Jetie Stone of Tuscaloosa, Ala., at Suearnoochee, Miss., May 22.

Deaths.

Frederick Christian Schaefer, M.D. Chicago Medical College, 1876, a member of the American Medical Association, Illinois State Medical Society, Chicago Medical Society, Chicago Medico-Legal Society, and Chicago Pathological Society; professor of anatomy and clinical surgery in Northwestern University Medical School for 9 years, professor of surgery Post-Graduate Medical School and Hospital; surgeon-in-chief St. Hedwig's Hospital; surgeon to Charity, Chicago and Post-Graduate hospitals; gynecologist to St. Elizabeth's Hospital; consulting surgeon to Mary Thompson Hospital and the Illinois Charitable Eye and Ear Infirmary, well known as a surgeon and teacher, died at his home in Chicago, June 3, from acute gastritis, after an illness of six hours, aged 55.

George W. Green, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1862, a member of the American Medical Association, and of the Michigan State Medical Society; assistant surgeon of the Twenty-eighth Michigan Volunteer Infantry in the Civil War; prominent as a specialist in diseases of the eye, ear, nose and throat, died at his home in Battle Creek, Mich., May 27, aged 67.

Henry M. Replogle, M.D. Rush Medical College, Chicago, 1895, a member of the American Medical Association, was injured in a runaway accident near his home in Udell, Iowa, May 27, and died a short time after from internal hemorrhage, aged 38.

Lyman M. Beckes, M.D. Medical College of Indiana, Indianapolis, 1887, died at his home in Vincennes, Ind., May 25, from septic meningitis following an operation for suppurative otitis media, after an illness of ten days, aged 42.

Henry John Hutchinson, M.D. University of Minnesota College of Medicine and Surgery, 1904, who was graduated May 28, was drowned by the capsizing of a boat in the Dalles of the St. Croix River, Minnesota, May 29, aged 25.

James Robinson Gray, M.D. Jefferson Medical College, Philadelphia, 1897, of Youngstown, Ohio, died at the home of his mother in Pittsburg, Pa., May 26, from pulmonary tuberculosis, after an illness of one year, aged 32.

Martin H. Head, M.D. Kentucky School of Medicine, Louisville, 1851, assistant surgeon of the Fourteenth Illinois Volunteer Infantry during the Civil War, died at his home in Carlinville, Ill., April 26, aged 77.

Rollo Campbell, M.D. University of Bishop's College, Faculty of Medicine, Montreal, 1887, of Montreal, died at the Western Hospital in that city, May 30, from typhoid fever, after an illness of three weeks.

Clinton D. Baker, M.D. Medical Department of Western Reserve University, Cleveland, 1892, committed suicide at his office in Conneaut, Ohio, May 26, by severing veins at his wrists and elbow.

Theodore Osgood Cornish, M.D. Vermont Medical College, Woodstock, 1851, one of the founders of the Thurber Medical Association, died at his home in South Boston, Mass., May 23, aged 80.

Arthur Maxwell Line, M.D. College of Physicians and Surgeons in the City of New York, 1899, died suddenly from heart disease at his home in Wilmington, Del., May 29, aged 33.

J. H. Turner, M.D. Albany (N. Y.) Medical College, 1845; surgeon of the First Wisconsin Volunteer Cavalry in the Civil War, died at his home in Berlin, Wis., May 26, aged 85.

Thomas N. Clark, M.D. Galveston (Texas) Medical College, 1871, died at his home in Reagan, Texas, May 20, from organic heart disease, after an illness of more than six years.

John C. Sill, M.D. New York University, New York City, 1848, ex-president of the Washington County Medical Society, died at his home in Argyle, N. Y., May 23, aged 80.

Clinton L. Shoemaker, M.D. Medico-Chirurgical College of Philadelphia, 1903, died at his home in Philadelphia, May 29, from spinal meningitis, aged 33.

Charles L. Parker, M.D. Albany (N. Y.) Medical College, 1892, died at his home in Onondaga Hill, N. Y., May 23, after an illness of six weeks, aged 47.

John L. Johnstun, M.D. 1840, surgeon in the United States Army in both the Mexican and Civil wars, died at his home in Craig, Mo., recently, aged 86.

James P. Gwynn, M.D. Southern Medical College, Atlanta, Ga., died at his home in Bogart, Ga., May 27, from malignant disease of the throat, aged 54.

Walter S. Jones, M.D. Detroit Medical College, 1881, died at his home in Corunna, Mich., May 31, from Bright's disease, after a long illness, aged 48.

Anna E. Park, M.D. Philadelphia, 1860, died from pneumonia at her home in New York City, May 30, after an illness of five days, aged 74.

N. S. Whetstone, M.D. Medical College of the State of South Carolina, Charleston, 1860, died at his home near Branchville, S. C., May 25, aged 73.

Marion C. Wells, M.D. Washington University School of Medicine, Baltimore, 1871, died from appendicitis at his home in Searcy, Ark., May 29.

Peter H. Pursell, M.D. University of Pennsylvania, Philadelphia, 1864, of Chicago, died at St. Louis, May 28, from apoplexy.

Orville A. Tillotson, M.D., died at his home in Titusville, Pa., May 24, from pneumonia, after an illness of one week, aged 47.

James M. Branson, M.D. Illinois, 1878, died at his home in Keenes, Ill., April 14, from an overdose of a drug, aged 67.

William L. Purple, M.D. Albany (N. Y.) Medical College, 1875, died at his home in Albany, N. Y., May 25.

James D. Wallis, M.D. University of Louisville, 1858, died at his home in Nashville, Tenn., May 25, aged 75.

Solon R. Boynton, M.D. Missouri, 1883, died at his home in Sparta, Ill., May 14, from diabetes, aged 54.

Silas C. Lybarger, M.D. Ohio, 1864, died at his home in Ganges, Ohio, May 20, aged 74.

Deaths Abroad.

E. J. Marey, M.D., the inventor of the sphygmograph, died at Paris, May 16, aged 74. His research on the physiology of the heart and respiration soon won for him international fame as his publications on the subject were issued. He invented the sphygmograph in 1860, and became professor of natural history at the Collège de France in 1867, where he continued his brilliant work in experimental physiology, and especially the application of instruments of precision in its study. He is one of the last to go of the brilliant group which included Claude Bernard, Brown-Séquard and Vulpian.

Gilles de la Tourette, M.D. professor agrégé at Paris, died at Lausanne May 23. He was one of the best-known Paris neurologists until his health broke down four years ago. His name is associated with the *maladie des tics*, which he was the first to describe. He was also editor of the *Iconographie de la Salpêtrière*.

P. Tommasoli, M.D., professor of dermatology and syphilography at Palermo, died there May 3, aged 46. Among his latest works were his communications on the advantages of intravenous injections of sublimate as a means of aborting syphilis.

A. Scherman, M.D., died at Budapest, April 28, aged 62. He was the official head of medical affairs in his city, and it is to his efforts that is attributed the reduction of the mortality from 42 per 1,000 when he assumed office, to the present death-rate of 18 per 1,000.

G. Karamitsas, M.D., professor of clinical medicine at Athens, died in Athens, May 2, aged 70. He studied medicine in Germany and translated some of the German text-books into Greek and was also the editor of the Greek medical journal *Asklepios*.

Dr. Vorster, director of the public insane asylum near Strasburg, was stabbed by one of the patients in April and succumbed to his injuries May 4. The patient had managed to make a dagger out of a scrap of metal.

C. De Vincentiis, M.D., professor of ophthalmology at Naples, died at Naples, May 28.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, for the week ending June 4, 1904:

Jean, George W., asst.-surgeon, ordered to Fort Jay, New York, for temporary duty.

Snoddy, Cary A., asst.-surgeon, relieved from duty as surgeon on the transport *Sherman*, to take effect on the next arrival of that transport at Manila, and will then report to the commanding general, Philippine Division, for assignment to duty.

Stiles, Henry R., asst.-surgeon, left San Francisco on sick leave of absence.

Harvard, Valery, asst.-surgeon general, and Lyster, Theodore C., asst.-surgeon, left West Point, N. Y., with cadets en route to the Louisiana Purchase Exposition, St. Louis.

Woodruff, Charles E., surgeon, left U. S. Army General Hospital, Presidio of San Francisco, on thirty days' leave with permission to apply for two months' extension

Gorgas, William C, asst.-surgeon general, relieved from duty as chief surgeon, Department of the East, and to report to Isthmian Canal Commission for duty.

DeWitt, Wallace, asst.-surgeon, relieved from duty at Louisiana Purchase Exposition, St. Louis, and ordered to Fort Washakie, Wym., for duty.

Cowper, Harold W., asst-surgeon, appointed first lieutenant and asst.-surgeon U. S. Army, to rank from May 19, 1904.

Torney, George H., deputy surgeon general, left San Francisco en route to Washington, D. C, with insane patients. Reported in person at surgeon-general's office.

Mason, Charles F., surgeon, left Fort Sam Houston, Texas, on four months' leave of absence.

Owen, Leartus J., asst. surgeon, assigned to duty at Fort Myer, Va.

Zinke, Stanley G., asst-surgeon, assigned to duty at Fort Riley, Kan.

Culler, Robert M., asst.-surgeon, assigned to duty at Fort Jay, N. Y.

Weed, Frank W., asst.-surgeon, assigned to duty at Fort McHenry, Md.

Wickline, William A, asst.-surgeon, assigned to duty at Fort Ethan Allen, Vt.

Miller, Albert L., contract surgeon, assigned to duty in the Philippine Division, and sailed from San Francisco for Manila on the *Sheridan* June 1.

Halsell, John T., contract surgeon, left Fort McIntosh, Texas, May 27, on leave of absence for one month.

Cooke, Robert P., contract surgeon, granted leave of absence for one month from Fort Wood, N. Y.

Jones, John F., contract surgeon, ordered from Fort Totten, N. Y., to Fort Jay, N. Y., for temporary duty.

Brown, Wilmont E., contract surgeon, relieved from duty at Fort Casey, Wash., and assigned to Fort Walla Walla, Wash., for duty.

Slater, Ernest F., contract surgeon left Fort Hancock, N. J., May 30, for temporary duty at Fort Howard, Md.

Kellogg, William V., contract surgeon, left Fort Sill, Okla., May 24, on sick leave for two months.

Chambers, William H., contract dental surgeon, ordered from Atlanta, Ga., to Fort Fremont, S. C., for two weeks' duty, and thence to Forts Moultrie, S. C., and Caswell, N. C., for one month each.

Voorhies, Hugh G., contract dental surgeon, directed to proceed from Fort Ethan Allen, Vt., to Fort Hancock, N. J., about June 15.

Kuhn, Charles F., contract surgeon, began leave of absence for two months from the Philippine Division June 1.

Rebert, Michael A., contract surgeon, assigned to duty as surgeon of the transport *Sumner*.

McCall, James H., contract surgeon, when relieved at Columbia Arsenal, Tenn., will proceed to Fort Moultrie, S. C., for duty.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending June 4, 1904:

Kite, I. W., surgeon, detached from the *Maine* and ordered to the Naval Hospital, Pensacola, Fla., for treatment.

Fauntleroy, A. M., asst.-surgeon, detached from the *Scorpion* and ordered home and to await orders.

Richardson, R. R., asst. surgeon, detached from the Naval Hospital, Pensacola, and ordered home to await orders.

Taylor, J. L., A. A. surgeon, detached from duty with naval recruiting party No. 6, May 28, and ordered to duty at the Naval Hospital, Pensacola, Fla.

Richardson, F. A., A. A. surgeon, detached from the Naval Hospital, Newport, R. I., and ordered to the *Scorpion* June 2.

Murphy, J. F., asst.-surgeon, detached from the *Isle de Cuba* and ordered home and to wait orders.

Owens, W. D., asst.-surgeon, ordered to the Naval Hospital, Newport, R. I.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the surgeon general, Public Health and Marine-hospital Service, during the week ended June 3, 1904:

SMALLPOX—UNITED STATES.

Alaska: May 17, Hoonah, 3 cases; Killisnoo, 2 cases; Juneau, May 15, 1 case.
Florida: Jacksonville, May 22-28, 2 cases.
Georgia: Macon, May 22-28, 3 cases.
Illinois: Chicago, May 22-28, 6 cases.
Iowa: Des Moines, April 1-30, 8 cases; Dubuque, May 15-28, 1 case.
Kentucky: Covington, May 22-28, 1 case.
Louisiana: New Orleans, May 22-28, 11 cases, 2 imported.
Maine: Jonesport, May 26, 23 cases.
Maryland: Baltimore, May 22-28, 5 cases, 1 death.
Michigan: May 22-28, Detroit, 2 cases; Grand Rapids, 2 cases.
Missouri: St. Louis, May 22-28, 4 cases, 2 deaths.
New Hampshire: Manchester, May 22 28, 3 cases.
New York: New York City, May 22-28, 1 case.
Ohio: May 22-28, Bucyrus, 13 cases; Dayton, 4 cases, 1 death; May 21-27, Cincinnati, 11 cases, 2 deaths; Cleveland, 2 cases; Hamilton, April 24-30, 6 cases.
Pennsylvania: Butler, April 24-30, 1 case; May 22-28, Johnstown, 5 cases; Philadelphia, 11 cases, 2 deaths; Pittsburg, 1 case, 1 death.
South Carolina: Greenville, May 15-28, 5 cases.
Tennessee: May 22-28, Memphis, 7 cases; Nashville, 8 cases.
Utah: Salt Lake City, May 15-21, 2 cases.
Virginia: Pocahontas, May 1-31, 2 cases.
Washington: Tacoma, May 17-23, 1 case.
West Virginia: Martinsburg, April 4-May 13, 20 cases, 1 death.
Wisconsin: Milwaukee, May 22-28, 7 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, May 1-7, 4 cases.
Belgium: Antwerp, May 8-14, 2 cases, 3 deaths.
Columbia: Barranquilla, May 2-16, 3 deaths.
France: May 8-14, Lyons, 2 deaths; Paris, 17 cases, 3 deaths.
Great Britain. May 8-14, Dundee, 2 cases; Edinburgh, 2 cases; Leith, 1 case; London, 26 cases; Newcastle-on-Tyne, 5 cases; Nottingham, 12 cases, 1 death; Glasgow, May 14-20, 11 cases, 3 deaths; Liverpool, May 15-21, 1 case; Sheffield, May 1-14, 4 cases, 1 death.
India: Bombay, April 27-May 3, 17 deaths; Calcutta, April 24-30, 5 deaths; Karachi, April 25-May 1, 4 cases, 2 deaths.
Japan: Nagasaki, April 21-30, 125 cases, 23 deaths.
Java: Batavia, April 17-23, 12 cases, 1 death.
Mexico: City of Mexico, May 9-15, 7 cases, 2 deaths.
Netherlands: May 15-21, Amsterdam, 1 case; Rotterdam, 4 cases.
Russia: Moscow, May 1-7, 12 cases, 3 deaths.
Spain: Barcelona, May 1-10, 6 deaths.
Straits Settlements: Singapore, April 10-16, 1 death.
Turkey: Constantinople, May 9-15, 3 deaths; Smyrna, April 25-May 1, 2 deaths.

YELLOW FEVER.

Costa Rica: Limon, May 28, present.
Mexico: May 15-21, Coatzacoalcos, 4 cases, 1 death, 2 cases imported; Merida, 3 deaths; Tehuantepec, 3 cases, 1 death; Jalupan, May 27, 1 case.

CHOLERA.

India: Calcutta, April 23-30, 103 deaths.

PLAGUE.

Arabia: Aden, May 31, present.
China: Canton, May 26, spreading; April 15, Fu Shan, 50 deaths; Sun Ui, 20 deaths.
Egypt: April 17-23, 42 cases, 23 deaths.
India: Bombay, April 27-May 3, 471 deaths; Calcutta, April 24-30, 270 deaths; Karachi, April 25-May 1, 242 cases, 206 deaths.
New Zealand: Auckland, April 27, still present.
Peru: Payta, May 30, present.

THE ATLANTIC CITY SESSION

LARGEST ATTENDANCE ON RECORD.

Atlantic City for a Second Time Demonstrates Its Qualifications as Convention City.

The fifty-fifth annual session of the American Medical Association at Atlantic City has made medical history and has been in many respects the most notable convention ever held. The reports show that up to Tuesday afternoon 2,240 members had registered, a registration already exceeding by 221 the highest attendance ever noted, namely, that of 2,019 at Atlantic City in 1900. Reports received by telegraph just before going to press inform us that the registration up to Wednesday afternoon was 2,715. For the first two days of the New Orleans session the registration was 1,771, or 469 less than that for Monday and Tuesday of this session. The total attendance for the last five years has been: 2,019 at Atlantic City in 1900, 1,806 at St. Paul in 1901, 1,425 at Saratoga in 1902, 1,993 at New Orleans in 1903, and 2,715 at Atlantic City up to Wednesday at 4 p. m.

ARRANGEMENTS EXCELLENT.

Committee's Work Well Done—Weather Fine and Cool.

Atlantic City has justified its reputation as a summer resort, and the members, after suffering from the heat and moisture en route and in Philadelphia, were revived and rejoiced by the cool ocean breezes. The Committee of Arrangements is everywhere commended for the excellence and thoroughness of its preparations and for the earnest work of its members.

DELEGATES MEET.

House of Delegates Hold Two Sessions Monday—Hear Reports of Officers and Committees.

The House of Delegates met Monday morning and afternoon and transacted much important business, a detailed report of which appears in this issue. The work went smoothly. A definite campaign for national incorporation was planned.

REVISED CONSTITUTION ADOPTED.

The Committee on Constitution and By-Laws, appointed in May, 1903, at New Orleans, made its report, which was adopted with only slight modifications, thereby adopting the revised Constitution and By-Laws.

OPENING MEETING.

The meeting was called to order by President Billings. Rev. William Aikman, Atlantic City, opened the meeting with prayer.

Welcome.

Addresses of welcome were delivered on behalf of the citizens of Atlantic City by Mayor Franklin P. Strong and on behalf of the local profession by Dr. Theodore N. Reed. The Governor of New Jersey was unavoidably absent. The first vice-president, Dr. G. C. Savage, Nashville, Tenn., made a graceful response to the addresses of welcome. Dr. B. C. Pennington, Atlantic City, then presented the report of the Committee of Arrangements.

The Walter Reed Memorial.

The President introduced Dr. William W. Keen, Philadelphia, who reported the work done by the committee on the Major Walter Reed monument. Drs. William H. Welch, Baltimore, and Theodore Diller, Pittsburg, paid warm and eloquent tributes to Major Reed, and Dr. Keen presided over the subscription for the memorial fund. Great enthusiasm prevailed, and about eight thousand dollars was subscribed.

Induction of President-Elect.

Dr. Frank Billings, Chicago, the retiring President, then introduced the President-elect, Dr. John H. Musser, Philadelphia, who delivered the Address of the President, which appears on page 1533 of this issue.

GENERAL MEETING.

Oration on Medicine.

The general meeting was held in the First Presbyterian Church at 7:30 Tuesday evening. Dr. George Dock of the University of Michigan, Ann Arbor, delivered the annual Oration on Medicine, taking for his subject, "Prognosis; Its Theory and Practice." It will be found on page 1539 of this issue.

Symposium on Research Institutions.

The inauguration of the new feature of symposia at general meetings was agreed to be of great value, and the symposium on "Institutions Doing Research Work for the Science of Medicine," which included reports from the Carnegie Institution, by Dr. John S. Billings, New York City; the Rockefeller Institute, by Dr. L. Emmett Holt, New York City; the Memorial Institute for Infectious Diseases, by Dr. Frank Billings, Chicago; the Harvard Research Work, by Dr. Harold C. Ernst, Boston, and the William Pepper Laboratory of Clinical Medicine, by Dr. Alfred Stengel, Philadelphia, was very well received.

SECTION MEETINGS.

Sections Well Attended and Running Smoothly.

The Sections began their work Tuesday afternoon. The largest attendance was at the sections on Practice of Medicine, Surgery and Obstetrics.

Section on Surgery and Anatomy.

Professor Hoffa of Vienna was introduced and read a paper which was received with interest.

Section on Ophthalmology

The work of this Section was unusually well illustrated and exceedingly instructive. The address of the chairman, Dr. Robert L. Randolph, Baltimore, "Thoughts Suggested by a Study of the Eye Injuries of Independence Day," was interesting, valuable and timely. Dr. H. V. Würdemann, Milwaukee, gave a demonstration of "Tumors of the Orbit" which showed deep study. He also gave a new classification of these tumors in accordance with the demands of modern pathology.

Section on Stomatology.

This Section opened with a symposium on Dental Education, participated in by the chairman, Dr. George F. Eames, Boston, who, in his address, discussed "The Value of Symmetry in the Development of Professional Character and Education"; Dr. Charles Chittenden, Madison, Wis., who considered "The Evolution of Standards in Dental Education"; Dr. A. E. Baldwin, Chicago, who reviewed "The Phases of Dental Education," and Dr. John S. Marshall, U. S. Army, San Francisco, who gave "A Retrogressive and Prospective View of Dental Education." The papers evoked vigorous and thoughtful discussion, and will all appear in The Journal of June 18.

Section on Nervous and Mental Diseases.

This Section was saddened by the death of its chairman, Dr. F. Savary Pearce of Philadelphia, which occurred May 27.

Section on Cutaneous Medicine and Surgery.

The first day's work of this Section included the address of the President, Dr. Henry G. Anthony, Chicago, on "The Developmental Defects of the Skin and Their Developmental Growths," which will appear in The Journal of June 18; and papers by Dr. R. A. McDonnell, New Haven, on "Falling of the Hair"; by Dr. John A. Fordyce, New York City, on "Report of a Case of Paget's Disease of the Gluteal Region"; by Dr. Louis E. Schmidt, Chicago, on "Reports of Several Interesting Dermatologic Cases"; by Dr. William A. Pusey, Chicago, on "Radium and Its Therapeutic Possibilities"; by Dr. M. L. Heidingsfeld, Cincinnati, on "Linear Nevi"; a demonstration by Dr. John V. Shoemaker, Philadelphia, of "A Remarkable Case of Xanthoma," and a paper by Dr. Ludwig Weiss, New York City, on "Treatment of Hyperidrosis, Especially of Hyperidrosis Pedum, with Permanganate of Potash."

Section on Laryngology and Otology.

In this Section the paper by Dr. E. Fletcher Ingals, Chicago, on "Tonsillectomy by Forceps and Snare, Thorough, Painless and Safe," awakened much discussion.

Section on Materia Medica, Pharmacology and Therapeutics.

The address of the chairman, Dr. Oliver T. Osborne, was entitled "The Scourge of Nostrums and Irregular Practitioners." The Committee on Proprietary Medicines, consisting of Drs. Harry H. Moody, Mobile, Ala., and William J. Robinson, New York City, and Prof. Carl S. N. Hallberg, Chicago, presented its report, after which the papers were presented; by Dr. Harvey W. Wiley, Washington, D. C., on the "Federal Supervision of Drugs," in which he considered the supervision of drug importations; objects of examinations, to prevent fraud and to determine rate of duty; the doubtful questions submitted to the Secretary of Agriculture; the specific provision by Congress for the study of drug adulterations in the Bureau of Chemistry of the Department of Agriculture, and the study of foreign vegetable drugs with a view to introducing their cultivation in the United States; the organization of the drug laboratory in the Bureau of Chemistry; the three classes of drugs presented for study: 1. Drugs of the U. S. P.; 2. Proprietary remedies of standard composition recognized as legitimate remedies protected by trade mark or patent, and not official, and (3) so-called patent medicines defying definite description, mostly worthless, though often containing standard remedies, sold less on their merits than on the extent of their advertising; the indictable aspects of some of these advertisements; the co-operation of the Postoffice Department and action of the Postmaster General on the report of the Department of Agriculture; the exclusion of fraudulent preparations from the mails in this way: the desired co-operation of pharmaceutists and pharmaceutic societies to secure for the medical profession remedies of standard strength, unadulterated and of known character, and the needlessness of secret remedies containing unknown substances and of only assumed properties and value; Dr. Joseph P. Remington, Philadelphia, on "The Eighth Decennial Revision of the Pharmacopeia of the United States," and Dr. William J. Robinson, New York City, on "The Relation of the Proprietary Remedies. How May Substitution Be Avoided and the Desired Preparation Obtained Without Unduly Advertising the Manufacturers?" who said that the relation of the physician to proprietary medicines should be that of a skeptical but unbiased investigator. He should, first of all, know what he is prescribing, never ordering any preparation with the composition of which he is unfamiliar. Manufacturers should be made to state the ingredients of their preparations. The preparation should be occasionally analyzed by those competent to do so, to confirm or disprove the manufacturer's claims. If the ingredients of the preparation are known and the physician is satisfied with the therapeutic results, then he should make sure that he gets just what he ordered. This may best be accomplished by openly and frankly patronizing only pharmacies where substitution is known not to be practiced. Where the physician is not sure that he may trust his pharmacist he is perfectly justified in selecting the lesser of the two evils—prescribing in original packages.

The discussion on these papers was active and general.

THE DAILY BULLETIN.

An edition of 5,000 copies of the *American Medical Association Bulletin* was issued Tuesday, Wednesday, Thursday and Friday, giving lists of registrations and announcements for each day.

OTHER ATLANTIC CITY MEETINGS.

American Association of Life Insurance Examining Surgeons.

At its annual meeting, June 6, the following officers were elected: President, Dr. Denslow Lewis, Chicago; vice-presidents, Drs. Charles H. Harbaugh, Philadelphia; Frank B. Cross, Cincinnati; Henry W. Dewey, Tacoma, Wash., and Henry W. Cook, Richmond, Va., and secretary and treasurer, Dr. W. H. Birchmore, New York City.

American Medical Editors' Association.

At the meeting June 7 the following officers were elected: Dr. Harold N. Moyer, Chicago, president; Drs. James Evelyn Pilcher, Carlisle, Pa., and Otho F. Ball, St. Louis, vice-presidents, and Dr. Joseph McDonald, Jr., New York City, secretary.

American Academy of Medicine.

The following officers were elected June 6: President, Dr. Winfield Scott Hall, Chicago; vice-presidents, Drs. H. Bert Ellis, Los Angeles; Richard A. Reeve, Toronto, Ont.; Lewis S. McMurtry, Louisville, and Maurice H. Richardson, Boston; secretary, Dr. Charles McIntire, Easton, Pa.; treasurer, Dr. Edgar M. Green, Easton, Pa., and assistant secretary, Dr. Alexander M. Craig, Columbia, Pa. Sir Patrick Manson was elected an honorary member.

Entertainments.

The entertainment provided included Section smokers and vaudeville, receptions to visiting ladies by the committee and by Mrs. John H. Musser, a yachting trip for the ladies, and musicales on Young's and the Steel Pier every evening.

AMERICAN MEDICAL ASSOCIATION.

Proceedings of the Fifty-fifth Annual Session, held at Atlantic City, N. J., June 7-10, 1904.

OFFICIAL MINUTES—HOUSE OF DELEGATES.

First Meeting—Monday, June 6.

The House convened in the High School Building, Atlantic City, New Jersey, and was called to order at 10:30 a. m. by the President, Dr. Frank Billings of Chicago.

Report of Committee on Credentials and Registration.

Dr. Simmons presented the report of the Committee on Credentials and Registration.

On motion of Dr. H. O. Walker of Michigan the report was adopted.

Address of the President to the House of Delegates.

President Billings then delivered the following:

The privilege of presiding over this House of Delegates affords me keen pleasure. The sessions of this body at New Orleans were remarkable for the amount of business which was brought before it and for the facility with which it was transacted. The entire proceedings were characterized by a uniform feeling of cordiality between the members of the House, which made the work of the chairman comparatively easy.

Many of the delegates of a year ago are here. I feel, therefore, that I am in the hands of friends. I know your strength; you appreciate my limitations. I anticipate, therefore, that this—my last day as your presiding officer—will be a lasting and pleasurable era in my memory.

During the last year, as the legal president I have transacted the necessary business of the Association. There has been no especial subject acted on which needs to be mentioned especially here.

The greater part of the work of the Association accomplished during the year you will hear from through the Board of Trustees, the Secretary, the Editor and through the various committees which will report to you during this session.

By a mutual arrangement with Dr. J. H. Musser, the supervision of the business preparatory to the meeting at Atlantic City was left to him. This was done for the reason chiefly that the president-elect resided so near Atlantic City that he could easily keep in touch with the chairman of the Committee of Arrangements.

I have appointed the various necessary committees which require the legal sanction of the president. In other instances I have requested Dr. Musser to appoint the committees and delegates to form societies, etc., who would serve naturally during his term of office.

This arrangement has resulted in no embarrassment whatever, and I have to thank the president-elect for the relief he has afforded me by assuming much of the portion of responsibility in the preparations for the meeting here.

While it is necessary that the legal president should appoint the various committees which serve during the interval between the meetings, and especially the Committee of Arrangements at the next place of meeting, it would seem wise to me if the understanding should be established that the president-elect each year would assume the responsibility of advising and controlling the Committee of Arrangements with of course the aid of the Secretary of the Association. By this means the president-elect would come in touch with people who have to do with the arrangements for the meeting over which he would preside, and he would be better fitted, in a measure, to assume his duties of President than if he had nothing whatever to do with the arrangement of the meeting until he should be inducted into office.

It must be evident to each one of you who was present at the meeting at New Orleans that an enormous work was done by the House of Delegates, and, as I have stated before, done with facility and dispatch.

It is a question if this business was not done with too precipitate an action in some instances and one must feel that perhaps we need some word of caution. It is true that last year each new resolution was referred without debate to the business committee from whom we had a report before the subject was discussed and passed on. This was a measure of caution, but inasmuch as all of the business was poured into the business committee, its members were overworked. No word of criticism of any act of that committee, of which I am aware, has been made and the committee did its work as well as could an equal number of any other men. But there can be no question that such an amount of work demanded of a few men for four days in succession would only be burdensome to them, but would probably render them less able to judiciously weigh the business of the association than it deserves. It seems, therefore, to me, that we should at once consider some method by which all matters which come before us may be acted on with greater deliberation than the method adopted at Saratoga and at New Orleans, with the business committee, affords. This can be done by the creation of several committees to act in the place of the one business committee.

This matter has been discussed by your committee on revision of the constitution, and it has been my fortune to be able to confer with the members of that committee. From my conference with that committee and with other members of the association, I desire to present to you a plan which we may at once adopt, if it meets with your approval, and begin our deliberations with reference of all of our business to the several committees instead of as formerly, to the old business committee. These committees I would call "reference committees," and the number may be increased or modified in name from year to year as the house may elect.

To the appropriate committee should be referred the resolutions, measures and propositions which are presented to you before final action should be taken, unless you should decide unanimously to act otherwise. Each of these committees should, as soon as possible after the adjournment of each session of the House, or during the session if necessary, take up and consider the business which may have been referred to it. The committee should be able to report on the business referred to it at the next session or when called on for a report by you. Three members of a committee should constitute a quorum.

I would suggest the following committees:

1. A Committee on Sections and Section Work, to which shall be referred all business relating to the sections.
2. A Committee on Rules and Order of Business, to which shall be referred all matters regarding rules governing the action, methods of procedure and order of business of the House of Delegates.
3. A Committee on Medical Education, to which shall be referred all matters relating to medical colleges and medical education. The members of the Medical Council shall be members ex-officio of this committee.
4. A Committee on Legislation and Political Action, to which shall be referred all matters relating to State and National Legislation, memorials to legislatures, to the United States Congress, to the President of the United States, etc. The members of the National Committee on Medical Legislation shall be members ex-officio of this committee.
5. A Committee on Hygiene and Public Health, to which shall be referred all matters relating to hygiene, public health, etc.
6. A Committee on Amendments to the Constitution and By-Laws, to which shall be referred all business relating to the subject.
7. A Committee on Reports of Officers, to which shall be referred the President's address and the Secretary's and Trustee's reports, and
8. A Committee on Miscellaneous Business, to which shall be referred all business not otherwise disposed of.

I am sure that with this arrangement the business brought before us will be conducted with much more satisfactory results than if we continue to have but one committee. It will afford work for many members of the House who are on these committees and no member will be overworked as have been the members of the Business Committee during the last two years.

I have deliberated over this proposition, and if the suggestion meets with your approval, and the plan is adopted, I report the membership of these committees as follows:

Committee on Medical Education.—Chairman, Victor C. Vaughn: George W. Webster, George M. Kober, Joseph D. Bryant, Charles M. Ellis.

Sections and Section Work.—Chairman, A. P. Ohlmacher: Henry E. Tuley, G. W. Guthrie, Casey A. Wood, A. E. Baldwin.

Rules and Order of Business.—Chairman, Charles A. L Reed; W. T. Sarles, Le Roy Long, S Jepson, John Champlin.

Medical Legislation.—Chairman, J N. McCormack; W. T. Bishop, J. Y. Porter, W. B. Dorsett, J. N. Hurty.

Hygiene and Public Health.—Chairman, J. N. Hurty; Henry B. Holton, S. T. Earle, Phillip Mills Jones, E. S. Patterson.

Reports of Officers.—Chairman, W. N. Wishard; D. E Nelson, I. [illegible] Gordon, S. C. Baldwin.

[illegible] *y-Laws.*—Chairman, M. L. Harris; A. N. Vance, D. S. [illegible], W. A. Jayne, W. L. Wills.

Miscellaneous Business.—Chairman, E. W. Walker; A. R. Craig, E. E. Dorr, A. D. Price, R. C. Moore.

Credentials.—Chairman, George H. Simmons; F. W. McRae, Samuel Bailey, Harold N. Moyer, R. P. M. Ames.

On motion of Dr. Walker of Indiana that part of the President's address about referring matters to reference committees was adopted.

On motion of Dr. Baldwin, Illinois, the recommendation of the President in regard to the President-elect having control of the scientific work and its preparation for the next meeting was concurred in.

Report of the Secretary.

The Secretary read his annual report as follows:

To the Members of the House of Delegates of the American Medical Association:

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

The membership on the date of my last report, May, 1903, was 13,545. During the year there have been added 2,413, and 919 have been dropped: 188 on account of death, 111 not eligible, 278 for non-payment of dues, 315 resigned, many of these on account of old age, and 27 were not found, leaving a net gain of 1,494. This makes the total membership on May 1, 1904, 15,039. Of the 2,413 names added to our membership list, 411 were new members, and 2,002 were originally subscribers to The Journal, and finally transferred to the membership list.

MEMBERSHIP IN STATE ASSOCIATIONS.

The number of members of the various state associations, except Nevada, Oregon and Wyoming, have been secured from the secretaries. Omitting these three states, the total membership is 44,012. We can estimate the three states not given as having a membership of 350, making the grand total 44,362. I give below the name of each state, with the number of members:

Alabama, 1,295; Arizona, 95; Arkansas, 711; California, 1,505; Colorado, 518; Connecticut, 605; Delaware, 134; District of Columbia, 447; Florida, 236; Georgia, 650; Idaho, 75; Illinois, 3,931; Indian Territory, 168; Indiana, 1,947; Iowa, 1,511; Kansas, 562; Kentucky, 1,361; Louisiana, 819; Maine, 461; Maryland, 715; Massachusetts, 2,681; Michigan, 1,672; Minnesota, 863; Mississippi, 606; Missouri, 1,400; Montana, 60; Nebraska, 658; New Hampshire, 350; New Jersey, 1,122; New Mexico, 63; New York, 1,704; North Carolina, 800; North Dakota, 115; Ohio, 2,451; Oklahoma, 163; Pennsylvania, 3,799; Rhode Island, 274; South Carolina, 207; South Dakota, 160; Tennessee, 1,004; Texas, 2,321; Utah, 89; Vermont, 403; Virginia, 1,096; Washington, 420; West Virginia, 600; Wisconsin, 1,185. Total, 44,012.

PHYSICIANS IN THE DEPARTMENT OF THE INTERIOR.

At the last session the Secretary was instructed to correspond with the Department of the Interior and to advise the House of Delegates at the next annual session in regard to according this service specific recognition. The correspondence has been with the Hon. Thomas Ryan, First Assistant Secretary, Department of the Interior, and he has kindly supplied us with a list of the names of the physicians connected with the various branches of the Department.

The number of physicians connected directly and indirectly with the Department of the Interior is as follows:

Board of Pension Appeals, 5; Bureau of Pensions, 86; Indian Agencies, 73; Indian Schools, 52; Government Hospital for the Insane, 13, and Freedmen's Hospital, 3; total 232.

Of these 107 reside in Washington, and consequently can obtain membership in the Medical Association of the District of Columbia. Those connected with the Indian Agencies and with the Indian Schools (125) are the only ones that may have difficulty in obtaining membership in an affiliated society. In glancing over the list containing these names, I find that probably three-fourths are located where membership in an affiliated society would be easily obtainable. Some of the physicians are sectarians and probably would not be considered eligible. Nevertheless, the existing conditions are such that there are quite a number, probably between 25 and 50, who could not without great inconvenience obtain membership in an affiliated society, and consequently, under present arrangements, are debarred from membership in the American Medical Association.

I am accompanying my report with a table which gives the names of the presidents, vice-presidents and orators for the past fifteen years for your information.

Respectfully submitted, George H. Simmons, Secretary.

Announcement of Committees.

The President then announced the following committees in accordance with the motion of Dr. Walker.

Committee on Medical Education.—Chairman, Victor C. Vaughn; George W. Webster, George M. Kober, Joseph D. Bryant, Charles M. Ellis.

Sections and Section Work.—Chairman, A. P. Ohlmacher; Henry E. Tuley, G. W. Guthrie, Casey A. Wood, A. E. Baldwin.

Rules and Order of Business.—Chairman, Charles A. L. Reed; W. T. Sarles, Le Roy Long, S. Jepson, John Champlin.

Medical Legislation.—Chairman, J. N. McCormack; W. T. Bishop, J. Y. Porter, W. B. Dorsett, J. N. Hurty.

Hygiene and Public Health.—Chairman, J. N. Hurty; Henry B. Holton, S. T. Earle, Phillip Mills Jones, E. S. Patterson.

Reports of Officers.—Chairman, W. N. Wishard; D. E. Nelson, I. J. Prouty, Seth C. Gordon, S. C. Baldwin.

Constitution and By-Laws.—Chairman, M. L. Harris; A. N. Vance, D. S. Fairchild, W. A. Jayne, W. L. Wills.

Miscellaneous Business.—Chairman, E. W. Walker; A. R. Craig, E. E. Dorr, A. D. Price, R. C. Moore.

Credentials.—Chairman, George H. Simmons; F. W. McRae, Samuel Bailey, Harold M. Moyer, R. P. M. Ames.

On motion, the reports of the President and Secretary were referred to the Committee on Reports of Officers.

Report of Business Committee.

The President called for the report of the Business Committeee.

Dr. Walker, Indiana, Chairman, said the committee had nothing to report at this time.

Report of Committee on Rush Monument.

. Dr. Holton, Vermont, read his report as Treasurer of the Rush Monument, which was referred to the Board of Trustees.

Report of Committee on Medical Education.

Dr. Arthur D. Bevan, Illinois, chairman, presented the report of the Committee on Medical Education, which was referred to the Committee on Medical Education.

REPORT OF COMMITTEE ON MEDICAL EDUCATION

Mr. President and Members of the House of Delegates: Your Committee on Education, consisting of Floyd W. McRea, Atlanta. Ga.; Rudolph Matas, New Orleans, La.; R. A. Marmion, United States Navy, Washington. D. C.; C. A. Daugherty, South Bend. Ind., and Arthur Dean Bevan, Chicago, Ill., chairman, respectfully submits the following report:

1. The American Medical Association was founded for the special purpose of obtaining a uniform and elevated standard of requirements for the degree of M.D.

2. The American Medical Association has so far accomplished little toward this end. The existing standards are not satisfactory as compared to those of the other great powers.

3. Our form of government makes it impossible, or improbable at least, to obtain national governmental control of medical education.

4. In absence of national governmental control efforts to make uniform and elevated the standard of medical education can be made most effective through the agency of the organized medical profession of the entire country, and such a body we now have in the reorganized American Medical Association.

5. The problem of using to the best purpose the weight and influence of the American Medical Association toward elevating medical education is a very large one and one which must be carefully worked out. This can best be done by a permanent committee or council specially created for this purpose.

6. We recommend the creation of such a council by the following addition to the By-laws, to be Chapter VI. Section 8:

CHAPTER VI.

Section 8.—The Council of Education shall consist of five members, to be appointed by the president and confirmed by the House of Delegates.

Immediately after the adoption of this by-law, one member shall be appointed to serve for one year, one for two years, one for three years, one for four years and one for five years. Thereafter one member shall be appointed each year to serve for five years.

The council shall organize, elect a chairman and secretary and shall adopt such regulations for the government of its actions as it deems expedient. It shall expend money or contract financial obligations only as shall be authorized in writing by the Board of Trustees.

The functions of the Council of Medical Education shall be:

1. To make an annual report to the House of Delegates on the existing conditions of medical education in the United States.

2. To make suggestions as to the means and methods by which the American Medical Association may best influence favorably medical education.

3. To act as the agent of the American Medical Association (under instructions from the House of Delegates) in its efforts to elevate medical education.

Report of Committee on Award of Association Medal.

Dr. L. S. McMurtry, Kentucky, read the report of the Committee on Award of the Association Medal, which was referred to the Committee on Miscellaneous Business.

REPORT OF THE COMMITTEE ON PRIZE ESSAY.

To the President and House of Delegates of the American Medical Association: Mr. President, the Committee on Prize Essay would respectfully report that soon after the adjournment of the Association last year, the following circular announcement was prepared and published in The Journal, and in all the other leading weekly medical journals of the United States, also in many monthly medical journals. This wide publicity was obtained through the courtesy of the medical press at the instance of the editor of The Journal of the American Medical Association.

The Prize Essay of the American Medical Association, a gold medal valued at $100, is offered annually by the American Medical Association for the best essay on any subject relating to medicine or surgery. The successful contestants for the prize may choose to receive (1) the gold medal, (2) a bronze replica of the medal and the remainder of the appropriation (about $90) in money, or (3) the entire amount ($100) in money. Since the Association annually sets apart the sum of $500 for original research, this prize is offered to stimulate the production of a superior practical essay based either on experimental studies or clinical investigations, or both. The committee will give preference to essays having the greatest brevity consistent with thorough consideration of the subject, and recommends that essays shall not exceed 500 words. The committee, while not restricting the choice of subjects, recommends as an important subject for consideration "The Therapeutic Value of the Digestive Ferments." Competing essays must be typewritten and must bear no mark revealing their authorship; but instead of the name of the author there must appear on each essay a motto, and accompanying each essay must be sent a sealed envelope containing the name of the author and bearing on its outer surface the motto of identification. No envelope will be opened by the committee until a decision has been reached as to the most deserving essay. The other essays will be returned to their respective authors. The committee reserves the right to reject all essays if none are found worthy of the Association medal. Competing essays must be in the hands of the chairman of the committee not later than April 1, 1904. Committee:: Lewis S. McMurtry of Louisville, Ky., chairman; Burnside Foster of St. Paul; M. H. Fussell of Philadelphia.

In response to this circular only one essay was received by the committee. The essay was submitted to the members of the committee for examination, and it is not deemed of sufficient merit to receive the Association's prize. Your committee has endeavored to avoid both extremes—that of fixing too high a standard of requirements on the one hand, requiring, on the other hand, sufficient scientific and practical value for the prize essay to be justly considered a positive addition to existing knowledge. With this standard in view your committee has decided that the essay submitted, while meritorious in many particulars, falls short of the standard fixed by the committee.

The chairman of your committee served as a member of the committee for several years with Dr. Hobart A. Hare of Philadelphia as chairman. During Dr. Hare's administration no essay was received by the committee so far as I am aware. Dr. Hare retired from the committee, we think, much discouraged as to the practicability of stimulating such research as was contemplated in founding the prize for an essay. As stated in the circular announcement just read, the Association annually sets apart the sum of $500 for original research, the Senn medal is annually offered for competition, so that the prize for an essay as contemplated in this instance has not stimulated the special study and investigation originally contemplated by the Association.

In the preparation of the announcement this year, which is included in this report, a definite subject of general practical interest was suggested as appropriate for such an essay in order that the object of the prize might be better understood, but this, too, has failed to attract competition.

In view of these facts your committee would recommend that the Association prize for an essay be abolished and the committee discharged.

All of which is respectfully submitted.

(Signed) L. S. McMurtry.
Burnside Foster.
M. H. Fussell.

Report of Committee on Award of Senn Medal.

Dr. M. L. Harris, Illinois, reported for the chairman of the Committee on Award of the Senn Medal that there had been no paper submitted to the Committee during the past year. (Referred to the Committee on Miscellaneous Business.)

Report of Committee on Transportation and Place of Session.

Dr. M. L. Harris of Illinois, chairman of the Committee on Transportation and Place of Session, reported that as the committee did not meet until the assembling of the General Session, he simply wished to report progress. The committee had done considerable work, but had not had time to complete it, and asked that further time be granted the committee.

On motion, the request was granted.

Journal Clearing House Commission.

Dr. H. O. Walker of Michigan presented a preamble and resolutions which were unanimously adopted by the Michigan State Medical Society, May 25, 1904.

Whereas, An exact knowledge of the composition and properties of substances used in the management of disease is essential to a physician's best success:

Whereas, Commercial push, by advertisement and drummers, persuades many physicians (often the very elect), to use and commend drugs, mineral waters, artificial foods, etc., etc., of unknown composition and effects:

Whereas, As it is impossible for the individual physician to verify the statements of sales agents, to separate fact from fancy.

he often uses substances quite unlike those indicated, to the discredit of himself and his art:

WHEREAS, The American Medical Association was organized to promote the exact knowledge and intelligent practice of its members:

Resolved, That the Board of Trustees, American Medical Association, is hereby requested to provide for the analysis of medicinal substances of unknown composition and undetermined effects, and to promptly publish the results in the Association JOURNAL:

Resolved, That the Board of Trustees be requested to appoint a "Journal Clearing House Commission," three in number, to serve without salary, with authority to have analyses made in reliable laboratories, by experts of recognized ability, or to equip a suitable laboratory and employ one or more competent experts, at a yearly expense not to exceed five thousand dollars.

This preamble and resolutions were unanimously adopted by the Michigan State Medical Society at its meeting in Grand Rapids, May 25, 1904, and its delegates were instructed to present the same to the American Medical Association at Atlantic City, and urge their adoption.

Dr. Harold N. Moyer, Illinois, moved that the resolutions be referred, first, to the Reference Committee on Medical Legislation. Seconded.

Dr. Harris, New York, moved as an amendment that the resolutions be referred to the Committee on the Establishment of a National Bureau of Medicines and Foods, and that action be postponed until after the report of that Committee on allied subjects. Seconded.

Dr. Moyer accepted the amendment, and the motion as amended was carried.

On motion of Dr. Ellis, California, the Secretary was instructed to procure a blackboard and have the names of the various committees written thereon at the opening of the afternoon session.

Report of Committee on National Legislation.

Dr. Charles A. L. Reed, Ohio, chairman of the Committee on National Legislation, read the report of this committee, and on motion, the report was referred to the same committee.

Report of the Committee on Medical Legislation.

Your Committee on Medical Legislation begs leave to report that it has held three formal sessions, namely, one in New York City, June 7, 1903, one in Washington, D. C., Feb. 11, 1904, and the third at Atlantic City, N. J., June 6, 1904, and that pursuant to clause in Chapter VII, Article III of the By-laws, it held a conference with the representatives of the various state medical associations, such conference having been held at Washington, February 12. Concerning the various questions which have been under consideration, your committee deems it important to report specifically but briefly concerning the following:

ORGANIZATION OF NATIONAL AUXILIARY CONGRESSIONAL AND LEGISLATIVE COMMITTEE.

At the meeting of the committee held in New York City, already alluded to, it was unanimously resolved, by virtue and in pursuance of the authority granted to the committee to devise means for the better promotion of needed medical legislation, to arrange for the appointment of an official correspondent in practically each county of the United States, this corps of correspondents to be known and designated as the National Auxiliary Congressional and Legislative Committee. It was thought that nominations for this large committee could best be made by the presidents of the various state medical associations, and a request was therefore issued to these officers asking for the name of a committeeman for each county in their respective states. The responses to this request were very general, only two positive declinations having been received, namely, one from Alabama, based on the ground that the president had no authority from his state association to exercise such kind office, and a second, from Massachusetts, the president of which association declined to make nominations on the ground that to extend such a courtesy would imply, in his opinion, the existence of an affiliation between that body and the American Medical Association, which affiliation, in his opinion, did not exist. In one or two other states the absence of a local organization has been given as an excuse for non-compliance, with the statement, however, that the necessary steps would be taken as speedily as possible. Nominations sent in, however, from the various states gave the central committee a list of about 1,940 names. Commissions were, accordingly, issued to each of these nominees, with the request that he serve in and for the county in which he resided until his successor was appointed and qualified, with duties prescribed as follows:

> It shall be the duty of each member of the National Auxiliary Congresional and Legislative Committee to bring all and only such matters of pending legislation as may be referred to him, either by the legislative committee of his respective state or territorial medical association, or by the Committee on Medical Legislation of the American Medical Association, to the attention of the medical profession and the people of his respective county, and by every honorable means, personal and political, individual and professional, private and public, direct and indirect, secure desired action thereon by his representatives in both branches, as the case may be, of the state legislature or of the congress of the United States. And it shall be his further duty promptly to report all such efforts on his part, first relative to state legislation to the chairman of the committee on legislation of his state medical association, and, secondly, relative to national legislation to the chairman of the Committee on Medical Legislation of the American Medical Association.

This extensive organization was practically completed by December, 1903, although there was no occasion to appeal to it until after the conference at Washington in February following.

NATIONAL LEGISLATIVE COUNCIL.

This conference, consisting of your committee and of one delegate from each affiliated state association and by representatives from the national medical services, was held in Washington, Feb. 11, 1904. A number of questions were brought to the attention of the meeting, among which were bills either maturing in the departments or actually pending before the congress as follows:

1. From the War Department: (*a*) An appropriation of $13,000.00 for book stacks at the Army Medical Museum and Library; (*b*) an appropriation for a general hospital for the army in the District of Columbia; (*c*) a bill to increase the efficiency of the Medical Department of the United States Army.

2. From the Navy Department: (*a*) A bill authorizing the establishment and organization of a corps of dentists in the U. S. Navy; (*b*) a bill for the establishment and organization of a nurse corps of trained women nurses in the U. S. Navy, and (*c*) an act to reorganize and increase the efficiency of the hospital corps of the navy of the United States, to define its duties and regulate its pay.

3. From the Agricultural Department: A bill for preventing the adulteration or misbranding of foods or drugs and for regulating traffic therein and for other purposes.

4. From the Treasury Department: A bill for an appropriation of $75,000.00 for the Hygienic Laboratory of the Public Health and Marine-Hospital Service, providing for a building and grounds.

In addition to the foregoing, cognizance was taken of (1) the then pending organization of the Panama Canal Commission, with the result that it was determined to make an effort to secure the appointment of a representative of the medical profession as a member of the commission itself, and (2) of the constitution of the general staff of the army, from which representation from the medical corps was then excluded.

The spirit of the conference was to give its own aid to invoke the influence of the profession only in behalf of such proposed legislation as seemed to have been the result of mature deliberation and to have arisen from the manifest exigencies of the various services. The position was taken that it would be much better for the profession to tender its influence in behalf of a comparatively few measures of unquestionable merit, rather than to support a large number of measures, the practicability of which could not be predetermined. In pursuance of the foregoing considerations the Legislative Council recommended the Committee on Medical Legislation to issue referenda on the following subjects:

REFERENDA.

Referendum No. 1.—This referendum, relating to the appointment of a medical representative on the Panama Canal Commission, was issued to the National Auxiliary Congressional and Legislative Committee, under date February 24, and requested each member of the committee to telegraph the president, urging such appointment and mentioning Col. W.

C. Gorgas, surgeon U. S. A., as a suitable person for the place, and to take such further action as might best be calculated to accomplish the object in view. The response to this referendum was spontaneous and enthusiastic. Your committee has been reliably informed that within 48 hours after it was issued more than 1,400 telegrams were received at the White House. Unfortunately, however, the law creating this commission prescribed that it should consist of seven members, four of whom should be engineers and one of whom should be a representative of the army and another of the navy, leaving the president absolute freedom to choose but a single member of the commission. The choice of this member had already been made, although your committee was not aware of the fact. It should be stated, furthermore, that your committee was in receipt of information which it considered reliable, to the effect that appointments on this commission would not be concluded until after March 1—a fact which accounts, in a certain measure, for the apparent delay in issuing the referendum. The result of this referendum is, however, considered salutary. In the first place it enabled your committee to demonstrate in the most conspicuous manner that the medical profession of the entire country is organized for legislative purposes; in the next place it emphasized the importance of sanitary administration, and has secured for those intrusted with these interests a degree of consideration and a status more satisfactory than would otherwise have been realized.

Referendum No. 2 was issued March 3, to promote the passage by the congress of bills relating to the medical service of the army as follows:

(A) "A bill to increase the efficiency of the Medical Department of the United States Army, and

(B) "An appropriation of $400,000 for a general hospital for the army in the District of Columbia."

The first of these measures, providing for an increase of the number of surgeons in the upper military grades and for the creation of a reserve medical corps, was rejected so far as these features are concerned by the general staff, but following representations by your committee was indorsed by Secretary Taft, and in that form went before congress.

Referendum No. 3 was issued March 10 to secure the united effort of the profession of the country in the final passage of a bill now pending in the United States Senate, entitled "A Bill for Preventing the Adulteration or Misbranding of Foods or Drugs and for Regulating Traffic Therein, and for Other Purposes," etc. Each auxiliary committeeman was requested to write to the chairman of the Committee on Manufactures, both of his United States Senators and to his representative, and, to secure the co-operation of his local profession, have resolutions adopted by his county societies, ask for editorial comment by local newspapers and send letters, copies of resolutions and newspaper clippings, expressive of public sentiment, to the chairman of the committee to be used by him in his championship of the bill in the senate.

Referendum No. 3 (supplementary) was issued because of the confusion which had arisen, growing out of the fact that, after the original referendum had been issued, the senate had substituted the text of its own bill for that which had been passed by the house. It was deemed by the committee that the senate bill was really the stronger of the two, the important difference being that it brought non-pharmaceutical remedies under the control of the government. The response to this referendum was very satisfactory. Senator Heyburn has in his possession a large number of letters and petitions which he has had issued in the *Congressional Record*, and an equally large number are being held until next session of the congress, when the pure food bill will come up for final hearing. Delay is considered advantageous to the friends of the bill, when we hope to counteract the influence of the opposition represented by the whisky trust and by the patent medicine trust.

MEDICAL REPRESENTATION IN THE GENERAL STAFF.

The question of securing a representation of the Medical Corps on the General staff of the Army, was taken up by a formal communication addressed to the secretary of war, under date March 1, 1904. The letter, it seems, however, was acknowledged by the assistant adjutant general March 12 and replied to by the chief of staff March 18. The latter communication transmitted the finding of the general staff, with the approval of the chief of staff, refusing the request which had been filed by your committee. The question was thereupon brought by your committee to the personal attention of Secretary Taft, with the result that an order was issued directing that a representative of the Medical Corps be detailed for service on the general staff. Your committee is thus able to report that one more invidious distinction which has long been maintained in the army against the Medical Corps, has been removed. This announcement is made with more pleasure in view of the cordial good spirit with which the change has been received by the other branches of the service.

THE WORK OF THE OFFICE.

It can be seen at a glance that the work entailed by this extensive organization and by the object that it attempts to accomplish, can not but be very laborious. As a matter of fact, more than 13,000 communications have been received, while nearly 30,000 have been issued from the office of your chairman. This has entailed a very considerable amount of printing, which, through the generous co-operation of the Board of Trustees, has been done in large part and will continue to be done in the office of The Journal. The clerical force necessary to carry on this correspondence, particularly during the congressional session, is an item of considerable expense, and if the work is to continue along the lines already projected, must be maintained. It is recommended, therefore, that necessary provision covering this item of expense and that involved for postage shall be made, either by specific appropriation or by general resolution, unless Chapter V, Section V. of the By-laws shall be construed to give the Board of Trustees proper discretionary power under such circumstances.

RECOMMENDATIONS.

(1) It is recommended that Article VII, Section III, of the by-laws be amended to read as follows:

(*a*) The Committee on Medical Legislation shall consist of three members appointed by the president, one for a term of one year, one for a term of two years, one for a term of three years, but whose successors shall each be appointed as vacancies occur for a term of three years, whose duty it shall be to represent before congress and elsewhere the wishes of this Association regarding any proposed legislation that in any respect bears on the promotion and preservation of the public health, or on the material or moral welfare of the medical profession.

(*b*) There shall be a National Legislative Council, which shall consist of the Committee on Medical Legislation, provided for in the preceding paragraph, and one representative from each state and territorial medical association and from each of the national medical services, such representatives to be nominated, respectively, by the presidents of the various state and territorial associations and by the chiefs of the respective national medical services, and appointed by the president of this Association. This council shall annually convene at the call of the Committee on Medical Legislation and shall consider questions of medical legislation as may be pending before the congress, or as may be referred to it by any state or territorial medical association, or by the chiefs of the national medical services, or that may be proposed by any of its members. Any action taken by the council shall be advisory in character and construed as a recommendation for the guidance of the Committee on Medical Legislation.

(*c*) There shall be a National Auxiliary Congressional Committee, which shall consist of one member of each county of the United States and one in each of the national medical services, appointment to such committee to be made by the Committee on Medical Legislation on nomination by the members of the National Legislative Council in conference with the councilors, or in the absence of the councilors, with the executive officers of the respective state associations. It shall be the duty of each member of the National Auxiliary Congressional Committee to bring all and only such matters of pending legislation as may be referred to him by the National Committee on Medical Legislation, to the attention of the medical profession and the people of his respective county and by every honorable means, personal and political, individual, professional, private and public, direct and indirect, secure desired action thereon by his representatives in both branches of the congress of the United States. And it shall be his further duty promptly to report all such efforts on his part to the chairman of the National Committee on Medical Legislation.

(2) It is further recommended that the entire organization of the American Medical Association bring itself to bear in securing members of the medical profession to become candidates for congress. One of the most serious difficulties with which your committee has to labor has been the complete absence of all medical representation on the floor of the House

of Representatives, while there are but two physicians in the Senate. This matter is of such distinct importance to the welfare of the medical profession, and to the welfare of the community, as represented by and through the medical profession, that every physician is urged to use his utmost influence, personal and professional, direct and indirect, in securing (1) the candidacy and (2) the election of colleagues of his profession to congress.

In conclusion, your committee, not only on its own behalf, but on behalf of the National Legislative Council and the National Auxiliary Congressional Committee, begs leave to thank the executive officers of the Association, the editor of THE JOURNAL and the Board of Trustees for cordial and appreciative co-operation in furthering the important work which it has had in hand. Respectfully submitted.

WM. H. WELCH,
W. L. RODMAN,
CHARLES A. L. REED,
Committee.

Dr. W. H. Sanders, Alabama, rose to a question of personal privilege, stating that the chairman of the Committee on National Legislation had mentioned in his report that Alabama had declined to appoint an auxiliary member of the Legislative Committee. He desired to say that the constitution of the state of Alabama was very definite, that it prescribed the duties of the President very definitely, and that those duties were extra-constitutional. Therefore, he did not feel authorized to make such an appointment, not from any intention of not participating in whatever national work might properly come before the association of Alabama or this body, but taking the view that under the constitution under which he was acting he had no such authority and declined to make the appointment.

Dr. Reed stated that the remarks made by Dr. Sanders were in direct line with what occurred in the report of the committee. From personal experience the committee succeeded in getting appointed tentatively a member of the committee through other channels, and the influence of Alabama had a very effective bearing on matters of legislation.

On motion of Dr. McCormack, Kentucky, the report of the Committee on Constitution and By-Laws was made the first order of business after the reading of the minutes at the next session.

Report of Trustees Postponed

On motion, the time for listening to the report of the Board of Trustees was fixed at approximately 3 p. m. tomorrow afternoon.

Report of Provisional Committee on the Establishment of a National Bureau of Medicines and Foods

Dr. E. Eliot Harris, New York, chairman, read the report of the Committee on the Establishment of a National Bureau of Medicines and Foods (provisional committee).

Michigan Resolutions Referred

Dr. Moyer, Illinois, renewed his previous motion that the resolutions offered by Dr. Walker of Michigan on the report of the Committee on the Establishment of a National Bureau of Medicines and Foods (provisional committee) be referred to the Reference Committee on National Legislation.

Seconded and carried.

Report of Committee on Reapportionment Postponed

Dr. W. S. Foster, Pennsylvania, Chairman of the Committee on Reapportionment, speaking for the committee, asked the privilege of reporting on Thursday, at which time the committee would be able to make a full report.

On motion the request was granted and the time for making the report was fixed as the first order of business on Thursday.

Report of Committee on National Incorporation Postponed

Dr. Bryant, speaking for the committee on National Incorporation, stated that the members of the Committee had not had an opportunity to meet, but were going to do so immediately after the adjournment of the meeting, and said the Committee would doubtless be prepared to report at the afternoon meeting.

Report of Committee on Organization.

Dr. McCormack, Kentucky, chairman, read the report of the Committee on Organization.

To the House of Delegates: The prompt and cheerful acceptance of your plan of organization by states and counties in every section of the country, and the uniformly gratifying reports of the results secured under its operation, make the account of our stewardship for the year a pleasant task.

A member of the committee has attended the annual meetings in a majority of the states, and in a number of them before and after their reorganization, and we are therefore in position to bear personal testimony to the progress which has been made.

Since the New Orleans meeting the standard constitution and by-laws, with such modifications as were necessary to adapt them to local conditions, have been adopted in North Carolina, Indiana, New Jersey, New York, Rhode Island, South Carolina, Maryland, Oklahoma and Delaware, in the order named. In addition, Minnesota, West Virginia and Kansas, which had partially reorganized in 1902, have also adopted the standard plan. As Alabama and Massachusetts have long had most of the important features of the Association plan, Pennsylvania, Virginia and Georgia are the only great states still operating under the old methods.

Michigan led the procession of states in this work last year, increasing the membership from 132 to about 2,100. Texas easily takes the banner this year, with an increase from 382 to 2,310, although several states have quadrupled their membership. What is probably still more significant as indicating the rapid growth of the movement, over 1,600 of the 2,830 counties in the United States are more or less completely organized.

While these results are almost phenomenal when compared with the past, they seem small in the light of what remains to be done before our organization is really complete. Few states except Alabama have over 50 or 60 per cent. of the eligible physicians even enrolled as members. After this preliminary work is completed, or while it is being done, and as a means to that end, good fellowship is being built up, the leaders of the profession in each county and state should join hands and put their heads together for such a utilization of all the forces at the command of a united profession for improving the condition of every physician and citizen of the jurisdiction.

This will cover every phase of professional work and interest, scientific, social, material and legislative, and, in the very nature of things, will never be completed. Instead, the assumption and proper discharge of these functions will constantly open up or develop new avenues of activity and usefulness. We are anxious that all this should be fully realized by you, and especially by the organizations you severally represent. The real test of our plan of organization will come in each state when the first outburst of enthusiasm has passed, and country societies, the foundation for everything, are likely to disappear as rapidly as they have been formed unless their usefulness to the rank and file of the profession can be demonstrated in a very broad way.

We earnestly commend these county societies to this Association and to every official and agency at its command.

RECOMMENDATIONS AS TO TIME OF MEETING OF STATE ASSOCIATIONS

To the House of Delegates:

GENTLEMEN:—The following instructions were given us at the New Orleans meeting:

Resolved, That the Committee on Organization be instructed to confer during the year with the governing authorities of the various state and territorial associations, and if possible, to report to this House next year some general plan for holding the annual meetings of these bodies in the fall, or at least at a time which will least conflict with the attendance of members at the sessions of the Association.

In obedience to the foregoing, we beg leave to report that, after an interchange of views, so far as practicable, with representatives of the state associations in all sections of the country, it seems advisable to recommend that all state associations hold their annual meetings during the fall and early winter months, beginning with September in the extreme North, and ending probably with December in the extreme South, and that this body continue to hold its meeting in the spring.

The Committee is frank to admit that it entered on the consideration of this matter with the expectation of reaching a conclusion and of making a recommendation exactly the reverse of this. That is, we expected to advise that the meetings of this Association be held in the fall and that all state organizations meet in the spring. This suggestion met with opposition almost everywhere, particularly from members connected with medical schools. They conceded the importance of systematizing and harmonizing the dates, but represented that it required an average of not less than ten days to attend the meetings of this Association, and that in the fall this would come at a time when most of the schools were just getting under way, and absence from their work would be most inconvenient and hurtful. They said, on the other hand, that the state meetings were close at hand, lasted but three days at most, and could be attended even by school men with as little inconvenience in the fall as at any other season

In thirty-five states the annual meetings are now held in the spring, most of them within the three or four weeks immediately *preceding the meeting of the* Association. As many of the best and busiest men can not well be away from home twice within so short an interval, they are forced to choose between the two, when they would like the privilege of attending both. Ten states now hold their meetings in the fall, and aside from the freedom from conflict with other meetings, the claim is made that the weather is more reliable, and that it suits the country physicians better, because the meetings come at a time when many of them need to go into the cities for their winter supplies.

It is also recommended that the dates of the meetings be arranged in *accordance with some definite system. This year* the meetings in Missouri, Iowa, Illinois, Ohio and Kentucky, neighboring states, all fell on the same day. If the meetings for a given section of the country, or for the entire country, could follow each other in some regular order, say one meeting early and one late in each week, as seems entirely practicable, it would be possible to add greatly to their interest by arranging for the attendance and a place on the program for the president, secretary, or one of the orators of this Association, for such of the state associations as desired it. The same privilege would also apply to fraternal delegates or distinguished *physicians of other states, if invited* to attend.

The Committee makes these recommendations only because it was directed to do so, and with a full appreciation of the delicacy of the position of this Association in regard to the matter. Even if approved by you, these recommendations are intended rather as a means of calling the attention of the state associations to the importance of such concert of action and agreement as will increase the interest and attendance at all the meetings and operate with least inconvenience to a majority of members.

The universal adoption of these recommendations would not in the least interfere with the plan of holding meetings of the new branch associations in the fall, as will be made clear in the report on that subject.

REPORT ON BRANCH ASSOCIATIONS.

To the House of Delegates:

Your Committee, to whom was assigned the duty of reporting on the advisability of dividing the country into branch associations, in accordance with the permissive provision contained in the plan of organization of this Association, and of suggesting a constitution and by-laws for such branches, and the states and territories which should be assigned to each, if such division was deemed advisable, begs leave to recommend that permission be given for the creation of seven branches, at the discretion of the governing authorities of the state associations composing them, so arranged as to cover the entire country.

Provisionally it is recommended that the branches be numbered and named, and that they shall contain or have assigned to them states and territories as follows:

1. New England and North Atlantic Branch.—New York, New Jersey, Connecticut, Rhode Island, Massachusetts, Vermont, New Hampshire and Maine.
2. Middle and South Atlantic Branch.—Pennsylvania, Maryland, Delaware, District of Columbia, Virginia, North Carolina and South Carolina.
3. Southern and Gulf Branch.—Georgia, Alabama, Mississippi, Louisiana, Arkansas, Tennessee and Porto Rico.
4. Mississippi Valley and Lake Branch.—Ohio, Indiana, Illinois, Kentucky, Missouri, Michigan and West Virginia.
5. Northwestern Branch.—Wisconsin, Minnesota, North Dakota, South Dakota, Nebraska, Montana and Wyoming.
6. Southwestern Branch.—Texas, Kansas, Oklahoma, Indian Territory, Colorado and New Mexico.
7. Mountain and Pacific Branch.—*California*, Oregon, Washington, Idaho, Nevada, Arizona, Alaska, Hawaii and the Philippine Islands.

A form of constitution and by-laws is submitted herewith. under which, as provided in the system proposed in our original plan, the presidents of the respective state associations become the vice-presidents of the branch associations, and the presidents of these larger bodies in turn become the vice-presidents of this Association. It is also provided that membership in the branch associations shall be voluntary, as it is in this body, but that no one shall be eligible for membership in any such branches who is not a member in good standing of his own county and state associations.

As the branch associations are organized, it is recommended that they hold their meetings in the fall, and at the same time for that of the state association of the jurisdiction in which the meeting is held. For instance, if the meeting of the Mississippi Valley and Lake Branch was to be held in Kentucky in 1905, it is advised that the scientific program of the two bodies for that year be merged, the house of delegates of each, of course, meeting separately for all purposes. The same arrangement would apply in the other states from year to year until the meetings had gone around. The bulk of the attendance under such a plan would be made up of the members in the state in which the meeting was held, as will be the case under any plan, but the attendance of leading men from other states would always be sufficient to add greatly to the interest of the state meeting for that year, and year after year this advantage would be extended to each state embraced in the branch.

In making the assignments of the states, existing organiza*tions, facilities for travel and natural affiliations* were considered so far as known and possible, but it is probable that advantageous changes can be suggested by members of this house who are better informed as to these matters in their own sections than we could hope to be.

The Committee realizes that the questions embraced in this report are important and far-reaching, and that some states and sections may not be prepared for several years to avail themselves of such an arrangement as is here suggested. Other sections are ready with old and valuable organizations, anxious to weave themselves into and become a part of our *uniform system, and some of them have already taken steps* looking to this end. If the recommendations are approved, nothing hasty or ill-considered can result, as the whole matter in each branch is conservatively left to the governing bodies of the state associations composing them, and membership is made entirely voluntary and limited to those who are members of their respective county and state associations.

Respectfully submitted.

J. N. McCormack,
G. H. Simmons,
P. Maxwell Foshay,
Committee.

Report of Committee on Portraits of Ex-Presidents.

The Committee on Portraits of Ex-Presidents reported progress.

Report of Committee on Sections and Section Work.

Dr. L. S. McMurtry, Kentucky, presented the report of the Committee on Sections and Section Work.

REPORT OF THE COMMITTEE ON SECTIONS AND SECTION WORK.

Dr. L. S. McMurtry of Kentucky made a verbal report of this committee. He said:

As chairman I have no formally-written report. but it may be of interest to the House of Delegates to have a brief *statement* in regard to the work of the committee. At the meeting held in Saratoga in 1902 Dr. Osler of Baltimore and Dr. Vaughan of Michigan and myself were appointed on this committee. which we mapped out at that meeting. We found that the section work of the Association, the importance of which could not be exaggerated, was very much in need of reconstruction. The committee undertook to bring the section work up to the standard of special organizations in the country which were engaged in similar work, and among the first things the committee realized was the importance. in the selection of chairmen and secretaries of the sections. to get men who were familiar with the work. and especially to have the secretaries somewhat permanent. This in great part has been done.

Another feature that we found so essential to the success of this work was that many of the sections overlapped: that is. there were many papers presented in one section which properly belonged in another section. and there was no *rule or regulation by which* the officers of the sections co-operated to separate and classify papers so as to make the work effective. Your committee took up this work. and at the meeting in New Orleans your committee recommended that there should be a meeting annually. in the interim between sessions of the Association. of the officers of the various sections together with the general officers of the Association. Such a meeting as this was held last October in Chicago. Nearly all the officers of the sections were present at this meeting. together with the general officers of the Association, and the work was gone over and arrangements made by which the officers of the sections could co operate one with the other and increase the efficiency of the sections, elevate the standard of requirements for papers and exercise some discretion in securing papers Arrangements were made for the classification of papers on kindred subjects together for discussion and to arrange the work of the sections after the manner of the great special organizations so that every section could of itself be a complete society, addressing itself to scientific research This has been productive of great good The officers of the various sections are now working in co operation, and I think we can justly say that never in the history of the Association has the work of the sections been in as good condition as that in which it will be entered on to morrow morning

Of course, there is much to be done and doubtless your new committee will take up the work and continue it But we have reason to feel gratified with the result of the co operative work of the sections and the advancement of it along the lines of perfection

On motion, the House of Delegates then adjourned until 2 p m

Second Meeting—Monday, June 6.

The House of Delegates reconvened at 2 p m, and was called to order by the President

On motion of Dr J N McCormack, Kentucky, the reading of the minutes of the previous meeting was dispensed with

Report of Committee on Miscellaneous Business.

Dr Edwin Walker, Indiana, read the following report of the Committee on Miscellaneous Business

ASSOCIATION MEDAL DISCONTINUED

The Committee on Miscellaneous Business concurs in the report of the Committee on the Award of the Association Medal, and recommends that the award of a medal by this Association be discontinued

SENN MEDAL COMMITTEE REPORT ACCEPTED

As to the report of the Committee on Award of Senn Medal, the committee recommends that it be received, no further action being necessary

Dr W T Bishop, Pennsylvania, moved that in taking action on the report of the committee the report be divided Seconded and carried

Dr Harold N Moyer, Illinois, moved that that section of the report dealing with the award of the Association Medal be concurred in and adopted Seconded

Dr W T Bishop moved that this part of the report be not adopted Seconded

After some discussion relative to the importance of continuing the award of the Association Medal, the motion of Dr Bishop was voted down, and the original motion of Dr Moyer to adopt was carried

It was moved that the second part of the report in regard to the award of the Senn Medal be adopted and the committee continued Seconded and carried

Report of Committee on Constitution and By-Laws

Dr P Maxwell Foshay, Illinois, read the report of the Committee on Constitution and By Laws, which was referred to the new Committee on Constitution and By Laws, Dr M L Harris, chairman

Report of Committee on National Incorporation

Dr Joseph D Bryant, New York, chairman, read the report of the Committee on National Incorporation, which was referred jointly to the Committee on National Legislation, to the Reference Committee on Medical Legislation, and to the Board of Trustees

PRELIMINARY REPORT TO THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION

GENTLEMEN —At the meeting of the American Medical Association, held at New Orleans in May, 1903, a resolution was adopted by the House of Delegates directing the appointment of a committee of five 'to get advice of the best legal talent in the United States as to whether or not the Association could be incorporated under an act of Congress, and to report at the next annual session of the House of Delegates"

In accordance with the resolution the following were appointed as a committee·

Dr Joseph D Bryant, New York, Chairman
Dr H L E Johnson Washington D C
Dr Leartus Connor, Michigan
Dr. D E. Fairchild, Iowa.
Dr C G. Kenyon, California
Dr Frank Billings, Illinois, *ex officio*

In the minutes of the meeting it immediately appears that the preceding resolution was amended by another which was "not seconded," authorizing "an expenditure of five hundred dollars for the purpose of obtaining opinions" Also it appears that during the discussion of the question "it was understood that no money should be expended for this purpose"

Under these somewhat perplexing circumstances the committee was constrained to limit its efforts to legal consultations that implied no pecuniary obligations whatsoever

Fortunately in this respect the committee was especially favored, since it had at its command for the asking the advice of one who for fourteen years had been familiar with the affairs of this country by reason of that length of service in the House of Representatives at Washington During this entire service in the House, this gentleman had served on the judiciary committee of the House, the last four of which (1898 92) he was chairman of that committee During much of this time the perplexing constitutional questions arising as the outcome of the Spanish American War were constantly under consideration in this committee This gentleman (who has been a United States judge since 1902) is, therefore, it is believed, amply equipped both by theory and actual experience in constitutional matters to solve for us this question beyond the possibility of reasonable gainsay. The judge unhesitatingly declares that the proposed incorporation is constitutional in all respects, and that it has been his duty and pleasure in many similar instances in the past to draft such like bills and to secure their passage on the floor of the House, and that at the present time these bills are operative in the affairs of the country and are a part of the laws of the land However, we can do no better at this time than to respectfully give our earnest attention to the written opinion of the gentleman on these questions

JUDGE RAY'S OPINION

'There can be no question that the proposed national or congressional charter for the American Medical Association as contained in the pamphlet entitled 'National Incorporation for the American Medical Association' at page 13 would (see last page of this report), if enacted into law, be free from all constitutional objections A long line of decisions pronounced by the Supreme Court of the United States has settled the legality of acts of Congress creating this class of corporations. These decisions are clear and free from conflict

'Under such a charter the incorporated body would be competent to acquire, by purchase, gift or otherwise, and hold or convey both real and personal property situated anywhere within the United States, and would be also authorized to hold its meetings and transact business anywhere within the limits of the Union It would be necessary, of course, that these places for holding meetings and transacting business be designated in advance from time to time and due notice given It would also be necessary and proper that the corporation have a principal place of business, but such main or principal place of business might be fixed in any state, and would not necessarily be located in the District of Columbia The advantages of a national incorporation when the purposes of the organized body are national in their scope and character and the membership is scattered throughout the entire nation, are manifest and important, and such an association as the American Medical Association, with a membership coming from forty five different states and our territories and the District of Columbia, ought not to be compelled to work within any one state or under the laws of any one state, as would be the case if incorporated under the laws of a state These considerations in similar cases have had controlling weight with the Supreme Court of the United States, as bringing the charter or act of Congress plainly within the scope and language of the constitution

"The persons created a body corporate by act of Congress constitute an independent body or corporation and such body can in no way interfere with or take away the property or other rights or the privileges of a corporation having similar aims or purposes heretofore or hereafter organized and incorporated under the laws of a state."

It therefore appears that no legal obstacle is interposed to securing actual incorporation under act of Congress of the American Medical Association.

Joseph D. Bryant, Chairman.

PROPOSED SPECIAL CONGRESSIONAL CHARTER FOR THE AMERICAN MEDICAL ASSOCIATION.

The living ex-presidents of the American Medical Association (by name), the presidents of each state association (by name), and then the Board of Trustees (by name), and such others as may be associated with them, and their successors, are hereby constituted a body politic and corporate by the name, American Medical Association, with perpetual succession; with power to sue and to be sued, complain, or defend in any court of law or equity; to make and use a seal, and alter the same at pleasure; to acquire, take by devise, bequests, or otherwise hold, purchase and convey, such real and personal estate as shall be required for the purpose of its incorporation; to select such officers and agents as the business of the corporation shall require, and make by-laws not inconsistent with the laws of the United States.

Said corporation is empowered to found, establish and maintain in the District of Columbia an institution for the dissemination of general medical information to and education of the citizens of the United States. Said corporation or its House of Delegates or Trustees may hold meetings, and conduct any business of the corporation wherever expedient within the United States with a like purpose, and for the further purpose of fostering the growth and diffusion of medical knowledge, of promoting friendly intercourse among physicians of the United States of America and of other countries, of safeguarding the national interests of the medical profession, of elevating the standard of medical education, of securing the enactment of medical laws, in directing and enlightening public opinion in regard to the broad problems of state medicine, and of representing to the world the practical accomplishments of scientific medicine.

On motion of Dr. Welch, Pennsylvania, a vote of thanks was extended to Judge Ray, New York, for his valuable legal opinion.

Adoption of Report on Medical Education.

Dr. Victor C. Vaughan, Michigan, presented the following report of the Reference Committee on Medical Education:

The Reference Committee approves and rcommends the adoption of the suggestion made by the Committee on Medical Education, and that it be referred to the Committee on Amendments to the Constitution and By-Laws.

On motion of Dr. E. Eliot Harris, New York, the report of the Reference Committee was adopted.

Reference Committee on Sections and Section Work.

The President called for the report of the Reference Committee on Sections and Section Work.

Dr. A. P. Ohlmacher, Ohio, Chairman, stated that the Committee had no report to make at present.

Report of Committee on Hygiene and Public Health.

Dr. J. N. Hurty, Indiana, read the report of the Committee on Hygiene and Public Health, which was referred to the Reference Committee on Hygiene and Public Health.

On motion the House of Delegates then adjourned to meet at 2 p. m., Tuesday, June 7.

Medical Organization.

Illinois.

Fox River Valley Medical Association.—At its seventy-eighth semi-annual meeting, held in Elgin, May 10, the committee appointed to arrange details of affiliation with the Illinois State Medical Society made its report and the constitution of the association was amended in accordance with the requirements of the state society and the American Medical Association.

Indian Territory.

The organization of the medical societies of Indian Territory is now completed in accordance with the plan of the American Medical Association. In lieu of counties, judicial district societies have been organized.

Iowa.

Johnson County Medical Association.—On May 26, 13 physicians of the county met at Iowa City and organized on the standard plan. The following officers were elected: Dr. Walter L. Bierring, president; Dr. Albertus J. Burge, vice-president; Dr. Joseph A. Valenta, secretary-treasurer, Dr. John B. Kessler, delegate to the state society and Drs. William R. Whiteis, Albertus J. Burge, and Laura H. Branson, censors, all of Iowa City.

Minnesota.

Freeborn County Medical Society.—On May 29 this society and the Albert Lea District Medical Society met in joint session at Albert Lea and the societies merged, under the name of the former, the members of the district society who lived outside of the county being made honorary members. Dr. Albert C. Wedge, Albert Lea, was elected president; Dr. William L. Palmer, Glenville, vice-president; Dr. George A. Stevenson, Albert Lea, secretary, and Dr. John P. Von Berg, Albert Lea, treasurer.

Montana.

Northeast Montana Medical Association.—Physicians of Chouteau and Valley counties, met at Chinook, recently and organized this society with Dr. Francis B. Atkisson, Fort Benton, president; Dr. Charles F. Hopkins, Chinook, vice-president, and Dr. Patrick H. O'Malley, Chinook, secretary and treasurer.

North Carolina.

Lenoir County Medical Society.—Dr. David T. Tayloe, Washington, councilor for the second district, met eight physicians of the county at Kinston, May 13, and assisted in the organization of a county society on the standard plan, with the following officers: President, Dr. Richard W. Wooten, Coahoma; vice-president, Dr. Charles B. Woodley, Kinston; secretary, Dr. William F. Hargrove, Kinston; treasurer, Dr. Romulus A. Whitaker, Kinston, and delegate to the state society, Dr. James M. Parrott, Kinston.

Rhode Island.

Woonsocket District Medical Association.—This association was organized on the standard plan, in April, and elected Dr. William C. Monroe, president; Dr. Elisha D. Clarke, secretary, and Drs. Elisha D. Clarke and William F. Barry, delegates to the Rhode Island Medical Society, all of Woonsocket.

Society Proceedings.

COMING MEETINGS.

Medical Society of Delaware, Lewes, June 14.
Wisconsin State Medical Society, Milwaukee, June 22.
Washington State Medical Association, Seattle, July 13-15.

AMERICAN LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL SOCIETY.

Tenth Annual Meeting, held in Chicago, May 30-June 1, 1904.

The Society met in the Banquet Hall of the Auditorium Hotel, under the Presidency of Dr. Norval H. Pierce, Chicago.

Dr. Frank Billings, Chicago, delivered an address of welcome.

Election of Officers.

The following officers were elected: President, Dr. F. C. Cobb, Boston; vice-presidents, Drs. Wm. Cheatham, Louisville, Ky., Thomas Hubbard, Toledo, Ohio, S. MacCuen Smith, Philadelphia, and W. B. Shields, St. Louis; secretary, Dr. Wendell C. Phillips, New York City; treasurer, Dr. Ewing W. Day, Pittsburg, Pa.

Boston was selected as the place for holding the next annual meeting.

President's Address.

The president, Dr. Norval H. Pierce, in his address, pointed out the great changes that had been wrought in the specialty during ten years. The well-rounded and successful specialist must not only possess special skill and dexterity with complicated mechanisms and functional tests, but he must have a broad surgical knowledge equal to that of the general surgeon, and an ever-accessible knowledge of regional anatomy superior thereto. He expressed the fear that the pendulum might swing too far in the direction toward radicalism. With the technic of external operations firmly within grasp, he asked, were not the members liable to resort to them prematurely—to forget that much might be done by more conservative local measures?

Dr. A. Logan Turner, Edinburgh, Scotland, read a paper on "The Pathology of Bone Cysts in the Accessory Sinuses of the Nose."

Chronic Otitis Media.

Dr. James F. McKernon, New York City, reported cases, and sounded a note of warning, in atypical cases, against delaying too long a search for the cause in the original focus of infection, when the patient did not progress well.

What the Laryngologist May Do for the Correction of Some of the More Common Forms of Defects of Speech.

Dr. G. Hudson Makuen, Philadelphia, said that an important field was neglected, namely, defects of speech, the treatment of which had either been entirely neglected or relegated to quacks. It had been estimated that every one of the 300,000 stammerers in the United States is a proper subject for medical supervision by the laryngologist, rhinologist and otologist. The exciting cause in 98 per cent. of all cases of stammering may be looked for in a morbid condition of some portion of the respiratory tract. Adenoids, enlarged turbinals and chronic rhinitis are causes of stammering. The laity and some physicians thought children would "grow out of" speech defects, and, therefore, they became nerve habits before any treatment was given. Treatment should be the removal of all physical obstructions to normal respiration, teaching physiologic breathing and the elementary sounds used in language; digestive disturbances should be corrected, tobacco and stimulants of all kinds interdicted, and the nervous system supported by nourishing food and plenty of sleep. Suggestion always plays an important part. Dr. Makuen had found the use of hypnotism of immense value. Stammerers should be taught to speak, and as far as possible even to think, in syllables.

Malignant Disease of the Upper Air Passages.

Dr. Chevalier Jackson, Pittsburg, said that serotherapy and ray-treatment were not yet proved of benefit. Unless total removal of infection was a reasonable possibility, no operation was justifiable except tracheotomy, esophagotomy or whatever else might be planned to prevent or postpone inanition or asphyxia. The curette had no place in the extirpation of laryngeal malignant disease. It rubs in the infection, as a rake buries seed in the soil. A clean cut with knife and scissors through healthy tissues beyond the invaded area is the best method.

Orbital Infection from the Ethmoid Cells, with Spontaneous Opening at the Inner Angle of the Orbit.

Dr. Carl E. Munger, New York City, said it was apparent to him that the number of cases recently reported was much less since the rhinologist had been developed, and our knowledge of intranasal diseases had increased and intranasal surgery had become more nearly perfected. This was undoubtely due to the earlier diagnosis made possible by more extended information as to ethmoid diseases, and the greater promptness with which the ethmoid region was attacked surgically.

Diseases of the Salivary Ducts and Glands and Their Treatment.

Dr. Robert C. Myles, New York City, reported cases, from which he argued (1) that it was necessary to make a thorough test of every known method to obtain a correct diagnosis in suspicious cases; (2) that the removal of calculi could best be accomplished by surgical procedures, preferably through the floor of the mouth; and (3) that it was always well, when possible, to probe and dilate the duct, and thus establish and maintain the normal flow of the salivary secretion.

The Relation of Diseases of the Stomach to Affections of the Mouth, Nose and Throat.

Dr. Robert Levy, Denver, said that three positive statements might be made clinically: 1. Certain affections of the upper air passages and their adjacent cavities are causative in a measure of some form of stomach disturbance. 2. Certain stomach disturbances are the cause of certain affections of the upper air tract. 3. The relationship existing between digestive disturbances and certain diseases of the upper air passages was so close that treatment must necessarily involve attention to both conditions.

Treatment of Tubercular Laryngitis.

Dr. S. E. Solly, Colorado Springs, said that most physicians were too timid in handling the tubercular larynx, resorting in their blindness to superficial treatment, and to sedatives in *their mistaken kindness, when in most cases they* had far better use radical measures.

Other papers were read and cases presented as follows:

"Uses of Rubber in the Treatment of Nasal and Antral Diseases," by Dr. Price Brown, Toronto, Ontario; "Tinnitus Aurium and Its Treatment," by Dr. W. S. Bryant, New York City; "Papilloma of the Larynx, with Report of a Case of Forty Years' Standing," by Dr. Wm. L. Culbert, New York City; "Chronic Empyema of the Sphenoidal Sinus," by Dr. H. Holbrook Curtis, New York City; "Purulent Otitis Media Complicating Typhoid Fever," by Dr. Ewing W. Day, Pittsburg, Pa.; "Adeno-Carcinoma Occupying All of the Sinuses, Nose and Orbits," by Dr. W. H. Dudley, Easton, Pa.; "Bezold's Variety of Mastoid Disease Complicating Diabetes Mellitus," by Dr. S. MacCuen Smith, Philadelphia; "The Value of Early Incision of the Membrana Tympani in the Treatment of Acute Suppuration in the Middle Ear," by Dr. Francis R. Packard, Philadelphia.

In the "Symposium on Malignant Growths of the Upper Air Passages," Dr. F. C. Cobb, Boston, discussed the nose and accessory sinuses; Dr. Max A. Goldstein, St. Louis, the mouth and pharynx, and Dr. D. Braden Kyle, Philadelphia, the pathology of the growths.

Cases were reported by Drs. Lewis A. Coffin, New York City; Joseph A. White, Richmond, Va.; Arthur B. Duel, New York City; James F. McCaw, Waterbury, Conn.; Edward B. Dench and T. Passmore Berens, New York City, cited four interesting cases of mastoiditis. The first was one of acute suppurative otitis media; mastoiditis; subperiosteal mastoid abscess; perisinus epidural abscess, which was operated on by the surgeon.

AMERICAN GYNECOLOGICAL SOCIETY.

Twenty-ninth Annual Meeting, held in Boston, May 24-26, 1904.

(Concluded from page 1510.)

Uretero-Lithotomy.

Dr. J. Wesley Bovée, Washington, D. C., gave the history of this operation and discussed the routes. He stated that all uretero-lithotomy wounds should be drained, because the urine was practically never normal, rendering wound infection probable. The possibility of urinary leakage subsequent to operation afforded another positive indication for drainage.

Nephrectomy for Primary Tuberculosis of the Kidney.

Dr. Hiram N. Vineberg, New York, said that tuberculosis of the kidney, both primary and secondary, was twice as frequent in women as in men. Renal tuberculosis in women was rarely associated with tuberculosis of the genital organs. A cystitis in women that resisted the topical applications of the silver nitrate solution by the Kelly method should be looked on with marked suspicion as being of a tubercular character, even though repeated urinalyses should show no tubercle bacillus. The differential diagnosis of a non-tubercular from a tubercular cystitis with the aid of a cystoscope was not as reliable as the therapeutic test outlined in the preceding sentence. Pronounced reddening or ulceration about the mouth of one of the ureters, with absence of other bladder changes, was held by some authorities as pathognomonic of tuberculosis of the corresponding kidney; while the sign was an important one, too much weight should not be attached to it in women. In most cases the removal of the diseased kidney would bring about practically a cure of the descending cystitis. He doubted the wisdom of the advice to cure the cystitis before undertaking the removal of the kidney. The prognosis of nephrectomy in renal tuberculosis in women was very good. Of the writer's four cases operated on, seven, five, two and one and a half years ago respectively, all were alive and in good health.

DISCUSSION.

Dr. J. Wesley Bovée said the surgeon should be sure that the opposite kidney could excrete urine for the whole body before removal of one tuberculous kidney. A nephrotomy might be done, and the kidney most markedly diseased drained, without taxing the other kidney to a great extent.

Dr. Philander A. Harris, Paterson, N. J., said that in cases of tuberculosis of the kidney it was difficult, where the bladder was corrugated and changed by the pathology present, to find the ureter; he suggested painting the entire field of the bladder with some solution, as Prussian blue. By this method he had succeeded in finding the ureters which he could not otherwise locate.

Dr. Seth C. Gordon reported two cases in which autopsy after the removal of one kidney revealed that only one kidney had existed.

Dr. J. M. Baldy said it was not uncommon to have practitioners ask if the ureters had been catheterized in cases of supposed kidney disease, and not infrequently a healthy kidney was palpated and found on one side which utterly failed to secrete with the patient under an anesthetic or without it. In some instances this failure on the part of the kidney to secrete was undoubtedly brought about by the influence of the anesthetic. He had had exactly the same experience a number of times in patients whose ureters he had catheterized, but to whom no anesthetic had been given.

Dr. Geo. M. Edebohls advocated that before removing a kidney an incision should be made on the opposite side to determine by actual inspection and palpation the presence of another kidney and its probable health, so far as could be determined macroscopically, before removing the diseased kidney. He had adhered to this rule in all nephrectomies performed since that time, and in one case he had saved a woman's life by so doing.

Dr. J. Riddle Goffe, New York City, reported a case in which removal of three inches of the ureter in connection with a tuberculous kidney, resulted in recovery and the patient is now in health eight years later.

Dr. Edward Reynolds, Boston, gave his experience of ten nephrectomies for tubercular disease, seven of them being complete nephro-ureterectomies, all successful, so far as operative mortality was concerned.

Hypertrophies and Inflammations About the Urinary Meatus.

Dr. Robert L. Dickinson, Brooklyn, read this paper at the afternoon session of the first day. The frequency and the suffering caused by these conditions give them an importance out of all proportion to their minute size. They are overlooked because hidden among folds of mucous membrane. The cure of chronic inflammation is only feasible by obliteration of the glands.

Surgery of the Female Urethra.

Dr. Ely Van de Warker, Syracuse, N. Y., said that after removal of the prolapsed portion of the urethra there was a marked tendency to recurrence unless the causal conditions were cured. Stricture of the urethra is common in women. Any condition that tends to produce linear or annular thickening leads to stricture. Eversion of the mucous membrane at the meatus may come from stricture; its surest cure is by dilatation.

Pyelitis Complicating Pregnancy.

Dr. Edwin B. Cragin, New York, said this cause of confusion with appendicitis, typhoid fever or salpingitis, occurs almost invariably on the right side. It is due to pressure on the ureter by the pregnant uterus plus an infection, due to the colon bacillus. The urine is acid, containing at first albumin and perhaps a few casts, soon followed by pus and bacteria. The prognosis is usually good. Induction of labor is seldom indicated. The medical treatment by urotropin, or allied drugs, with ice-bag over the kidney, fluid diet, and large draughts of water, is usually sufficient.

A Second Case of Puerperal Eclampsia Successfully Treated by Renal Decapsulation.

Dr. George M. Edebohls, New York City, reported a case in which the convulsions were arrested, the flow of urine was reestablished, and a threatened death from uremia was averted. Renal decapsulation thus became a rival of forced delivery in cases of puerperal convulsions of renal origin.

Repair of Lacerations of the Cervix Uteri.

Dr. Edward P. Davis, Philadelphia, on the second day, read the first paper of a symposium. In his experience immediate closure of the cervix has given no inconvenience to the mother, and has been followed by excellent results. This operation is not advised for those who do not practice obstetrics with good surgical technic, and who are not competent to operate on the genital tract.

Dr. Robert L. Dickinson, Brooklyn, read a paper urging that no complicated or considerable perineal injury should be repaired at the close of labor, but three to five days later, preferably on the fifth day.

Dr. J. M. Baldy, Philadelphia, read a paper stating that if the parts were preserved from infection, the greater part of a tear in the cervix would heal spontaneously, and the rest of it would remain perfectly healthy. The lips would remain uninfiltrated, of normal size and thickness, with no eversion and no erosion of the lining mucous membrane. In such a case there would be no untoward symptoms and no bad effects whatever. He had no part in the belief that lacerations of the cervix produced carcinoma.

President's Address.

Dr. Edward Reynolds, Boston, in his presidential address, stated that the use of the printed abstract published beforehand had of late become increasingly prominent in many societies, and in the British Medical Association this use of the abstract had reached its highest point. It was seldom wise to adopt wholesale the regulations of other organizations. It was usually better to let changes follow a more gradual and natural evolution under the needs of the individual assembly, but the methods of the English association were worth a passing consideration. He said that a member of the British Medical Association who desired to present a paper at one of its meetings must put it in the hands of the secretary complete and in the form in which he desired its publication a number of weeks before the meeting, and the communication might be of any length he chose. A paid secretary, a qualified and experienced medical author, then abstracted each paper in the form and length which he considered best fitted for its public delivery. This official then read the abstracts to the society as they called on the program. Such a reading inaugurated each discussion, and the member whose ideas had been thus succinctly set forth before his associates took part in the discussion and closed it. The ideas of individual members by this method were better and more intelligently presented than if they had read their complete papers. Time was economized, full debate was encouraged, and the members had the advantage of publishing to the world papers in which their points were set forth at the fullest length and without time limitation. He recommended that the society give this method, or a modification of it, a year's trial.

The Preventive Treatment of Pelvic Floor Lacerations.

Dr. J. Clifton Edgar, New York City, said that the causal factors should be prevented, namely: Too rapid expulsion of the fetus; relative disproportion in size between the presenting part and the parturient outlet; a faulty mechanism of labor. He recommended preliminary digital stretching of the vulval outlet in primipara.

Immediate Repair of Lacerations of the Perineum.

Drs. Lapthorn Smith, Montreal, and **Henry C. Coe**, New York City, advised immediate repair, and the former advised placing the sutures before the tears occurred, so as to bring the tissues together as before the tear.

Uniformity in Pelvic and Cranial Measurements.

Dr. A. F. A. King, Washington, D. C., said that the measurements of the normal pelvis and fetal head are indefinite, and proposed an ideal or hypothetical head and pelvis on the dimensions of which all authorities may agree. A committee was appointed by the president to consider the matter and report at the next annual meeting.

Symposium on Non-Operative Local Treatment in Gynecology.

Dr. Willis E. Ford, Utica, N. Y., said that the nervous habit could not be cured by surgery, and that local irritations ought to be treated by skilled gynecologists and not allowed to develop either the mental or physical ailments which were so common a result.

Dr. Walter P. Manton, Detroit, Mich., said that three factors were largely responsible for the neglect of medical gynecology: 1. The average physician's lack of knowledge in the accurate diagnosis and local treatment of pelvic disease. 2. The allurements and fascinations of surgery. 3. Competition in practice.

Treatment Preparatory to Operation.

Dr. Henry C. Coe, New York City, questioned the actual value of the hot vaginal douche, local applications to the vaginal fornix, treatment of the ectopic cervix, etc., previous to trachelorrhaphy, since the diseased tissue would all be removed at once by amputation. At the same time, he admitted the remarkable results often observed as regards the absorption of extensive pelvic exudates. Acute and subacute inflammations in and around the adnexa form the real contraindication to operation, and doubtless surgeons are not always as careful as those of the former more conservative generation in selecting their cases. Competition and the rush of modern life are responsible for some ill-advised operations, minor, as well as major.

The Value of Post-Operative Local Treatment.

Dr. J. Riddle Goffe, New York City, said the experience of all observers was that local treatment relieved congestion, pain and discomfort, inaugurated, hastened and accomplished the absorption of edema, plastic exudate, adhesions and pseudohypertrophy. If it would relieve these conditions, how much more certainly would it prevent them.

Dr. Chas. Sedgwick Minot, Boston, discussed "The Implantation of the Human Ovum in the Uterus."

Bathing During the Menstrual Period.

Dr. J. Clifton Edgar, New York, presented the following conclusions on this subject:

> 1. All forms of bathing during the menstrual period are largely a matter of habit, and usually can be acquired by cautious and gentle progression, but not for every woman does this hold good, and surf bathing, where the body surface remains chilled for some time, should always be excepted. 2. A daily tepid sponge bath (85 to 92 F.) during the menstrual period is not only a harmless proceeding, but is demanded by the rules of hygiene. 3. In the majority of, if not all, women tepid (85 to 92 F.) sponge bathing after the establishment of the menstrual flow, namely, second or third day, is a perfectly safe practice. 4. Furthermore, in most women the habit of using the tepid shower or tub bath after the first day or two of the flow can with safety be acquired.

The Nature of the Indications for Operation for Fibroid Tumors of the Uterus.

Dr. Chas. P. Noble, Philadelphia, presented a table of 1,188 cases of fibroid tumors operated on, and said that they showed the classical teachings concerning fibroid tumors to be erroneous. These teachings were that fibroid tumors of the uterus were benign growths, which usually produced but few symptoms, and which after the menopause underwent retrogressive changes, becoming smaller or disappearing; that the chief danger of fibroid tumors consisted in the fact that at times they caused hemorrhages from the uterus, and that rarely they cause trouble because of their size or on account of pressure on adjacent viscera. At least one-third of the women having fibroid tumor would have died had they not been submitted to operation.

Treatment of Gonorrhea.

Dr. Henry T. Byford, Chicago, advocated prolonged irrigations with hot water as a basis, and spoke of frequent injections of hot water as a substitute for prolonged irrigations. He referred to hydrogen dioxid and unirritating germicidal solutions as substitutes for plain water injections.

ASSOCIATION OF AMERICAN PHYSICIANS.

Nineteenth Annual Meeting, held at Washington, D.C., May 10-11, 1904.

(Concluded from page 1510.)

Types of Splenic Anemia or Splenomegaly.

Dr. Alfred Stengel, Philadelphia, reported cases. One was of a colored woman, aged 25, perfectly healthy, who had had an abdominal tumor for five or six years, which was found to be due to an enlarged spleen. There was no history of malaria. A splenectomy was done and, in spite of an intercurrent pneumonia during convalescence from the operation, the patient recovered perfect health. The blood after the operation showed a reduction of the polymorphonuclear leucocytes, and an increase of the lymphocytes and the transitional cells. The spleen showed a large number of umbilicated nodules, which were hard and solid. On section these nodules were seen to be of a neoplastic character, and were found to represent alveolar spaces filled with endothelial cells and giant cells. There was no necrosis; there were no tubercle bacilli; there were neither bacteria nor protozoa. The organ looked as though some infective process was responsible for the condition, which Stengel considered to be a primary splenomegaly. While syphilis is possible, he did not seriously consider it.

DISCUSSION.

Dr. William Osler, Baltimore, said that there is a great deal of difficulty in differentiating between the various forms of enlargement of the spleen. Out of the 9 cases that he had seen recently of enlargement of the spleen with anemia, he had cases that belonged to four classes: (1) primitive splenomegaly; (2) chronic splenic anemia, characterized by enlarged spleen, secondary anemia, leucopenia and pigmentation; (3) enlarged spleen, with the early occurrence of liver symptoms; and (4) splenic anemia, which subsequently developed into pernicious anemia.

Dr. George Dock, Ann Arbor, Mich., said that we should be doing more in the way of operation in these cases. It ought to be possible to separate endothelioma from the other cases, and to offer those patients the benefit of a splenectomy.

Dr. B. W. Sippy, Chicago, said that he had seen a case of enlarged spleen, which was diagnosed splenic anemia, which after operation showed a decided improvement in the blood picture. The spleen showed the ordinary splenic hyperplasia.

Dr. Richard C. Cabot, Boston, said that there is no evidence that any anemia is due to malnutrition alone.

Dr. William Osler, Baltimore, said that in the cases of enlarged spleen in men returned from the tropics, search should be made for the Leishman-Donovan blood parasites.

Dr. Alfred Stengel emphasized the fact that the third patient reported was in the best of health before the operation and presented no sign of malnutrition.

Trypanosomes.

Drs. F. G. Novy, W. J. McNeal and **C. B. Hare**, Ann Arbor, Mich., read a paper entitled "The Cultivation of Trypanosoma Evansi," which appeared in The Journal May 28.

Drs. F. G. Novy and **W. J. McNeal**, Ann Arbor, Mich., read a paper entitled "The Agglutination and Filtration of Trypanosomes."

Zonal Necrosis of the Liver.

Dr. E. L. Opie, Baltimore, said that the hepatic lobule may be divided into three zones, each of which may be the seat of coagulation necrosis affecting the liver cells. In 14 cases this necrosis was found between the center and the periphery of the lobule, while in other instances the area of necrosed cells was limited either to the peripheral zone or to the central area. Such necrosis is dependent on the presence of toxic substances in the blood, and the distribution of the lesion is the result of the conditions of the circulation within the organ. By experimental injections in the lower animals, it is possible to demonstrate the existence of this subdivision of the liver lobules into three zones. The cases of necrosis in the peripheral zone seen in the human subject were often associated with eclampsia. Out of 9 cases in which necrosis was situated in the middle zone, 6 were associated with acute peritonitis, 3 due to streptococcus, and 3 were associated with gastrointestinal lesions. In case of pernicious vomiting in the third month of pregnancy, midzonal necrosis was found which resembled icterus gravis, and which was accompanied by fatty degeneration in the central portion of the lobule. When regeneration takes place, the new cells arise from the cells in the periphery of the lobule which have escaped necrosis.

Addison's Disease with and without Adrenal Tuberculosis.

Dr. C. F. Withington, Boston, read this paper. The symptom-complex known as Addison's disease is more likely due to suspension of the function of the suprarenal gland than to any anatomic lesion. The author divides the cases of this complaint and the lesions of the adrenal body as follows: I, Cases with bronzing; A, adrenal tuberculosis, commonest type. B, Non-tuberculous lesions of the adrenal body (1) atrophy, (2) interstitial inflammation, (3) carcinoma, (4) occlusion of vein, (5) hemorrhage. C, No adrenal disease (1) with lesion of the semilunar ganglion, (2) with no lesion of the semilunar ganglion, (3) pigmentation, not Addison's disease. II, Cases without skin bronzing. A. Adrenal tuberculosis (1) with tuberculosis elsewhere in the body, (2) without tuberculosis elsewhere in the body. B, Adrenal disease, not tuberculous; (1) carcinoma, (2) tumors, (3) necroses.

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. E. L. Trudeau, Saranac Lake, N. Y.; vice-president, Dr. Frank Billings, Chicago; secretary, Dr. Henry Hun, Albany; recorder, Dr. S. Solis Cohen, Philadelphia; treasurer, Dr. J. P. C. Griffith, Philadelphia; councilor, Dr. F. Forchheimer, Cincinnati.

Book Notices.

Applied Materia Medica. A Text-book Intended for the Use of Nurses in Hospital Training Schools. By J. Henry Schroeder, Ph.G., M.D., Formerly Lecturer on Materia Medica in the Jewish Hospital Training School for Nurses, Cincinnati. Cloth. Pp. 113. Cincinnati: Robert Clarke Co.

A special work like this will be found of advantage to an intelligent woman engaged in the profession of nursing. As a text-book for training schools it gives as full information as is needed by nurses.

Immune Sera. Hemolysins. Cytotoxins and Precipitins. By Professor A. Wassermann, M.D., University of Berlin. Authorized Translation. By Charles Bolduan. M.D. First Edition. First Thousand. Cloth. Pp. 77. Price, $1.00. New York: John Wiley & Sons. 1904

Wassermann takes up the principles and theories of action of the immune sera, and writes especially for those who are so busily occupied in practical medicine that they have no time to follow the intricate experiments on which these principles and theories rest. Consequently experimental details are omitted and the subject is presented in a consecutive readable form, the style of which has in no way suffered by the translation. The hemolytic sera are given especial consideration; they are of great importance inasmuch as many of the principles of immunity have been worked out in connection with them. The Ehrlich side-chain theory, and the various terms used in connection with immunity, such as amboceptor, complement, anticomplement, etc., are given lucid expositions. A second section treats of other cytotoxic sera, such as those derived by immunization with leucocytes, or nervous tissue; reference is made to possible practical application of such sera. The chapter on precipitins deals with those sera which have the power of precipitating albumins from various sources, and with their practical uses.

The Therapeutics of Mineral Springs and Climates. By I. Burney Yeo, M.D., F.R.C.P., Emeritus Professor of Medicine in King's College. London. Cloth. Pp. 760. Price, $3.50 net. Chicago: W. T. Keener & Co. 1904.

The work is divided into two parts, the first being devoted to a study of mineral springs taken up in alphabetical order. Resorts of minor importance appear in smaller type and are described briefly, which gives to the reader the advantage of the author's experience and knowledge as to the relative importance of the various springs. In the first chapter the author has discarded the terms "muriated" and "acidulous" in his classification of springs, as being misleading and obsolete, and while he makes no sharp lines in his classification, he regards the following as the most practical one: 1. Indifferent thermal waters characterized by their temperature, varying from 80 F. to 150 F., by their feeble mineralization and by their great softness. 2. The common salt waters, including not only sodium chlorid in varying strength, but other chlorids and the bromids and iodids. 3. The alkalin waters, containing sodium bicarbonate alone or combined with sodium chlorid and sodium sulphate. 4. The bitter waters, the chief constituents of which are the sulphates of magnesium and sodium. 5. The iron or chalybeate waters, the iron occurring in the form of the bicarbonate. 6. The earthy or calcareous group containing the lime compounds. 7. The sulphur waters—a very large group. 8. The arsenical waters, which contain arsenic in varying proportions, either arsenious acid or the bromid and iodid of arsenic. The author then takes up the modes of application and action of mineral waters, together with their curative properties. In the second part he treats of climate and climatic resorts, sea or mountain, the application and selection of suitable climates.

A Text-Book of Physiology. By Isaac Ott, A.M., M.D., Professor of Physiology in the Medico-Chirurgical College of Philadelphia. With 137 Illustrations. Cloth. Pp. 563. Price $3.00 net. Philadelphia: F. A. Davis Company.

This is well adapted to the purposes for which it was written, namely, a student's "Elementary Work Containing the Chief Facts of Physiology Which are Necessary to the Student Who Wishes to Apply Them in the Practice of Medicine." Professor Ott has used good judgment in his choice of physiologic facts to present to the student of medicine. The advantage of a brief manual for the student is that it is presumed to contain only the facts of fundamental importance which would naturally be presented and emphasized by any teacher of physiology. This method of presenting the subject leaves to the teacher the privilege of introducing such supplementary matter as may seem wise. If a voluminous text-book be put into the hands of the student the teacher is forced to one or the other of the two alternatives: He must either omit a considerable portion of the text and introduce matter which to him may seem more important; or he must require the student to master the whole text as written, thus subordinating his own individuality and that of his department to that of another, namely, the author of a text-book. In the light of these facts, one must commend Professor Ott's work on physiology as well adapted to the use of the average medical student. The chapters on digestion and absorption precede those of blood, circulation and respiration, an arrangement which is a more logical one than that usually followed. While this arrangement has its advantages, it has the disadvantage of introducing the student to intricate problems of chemistry at the beginning of his course in physiology, which is usually the beginning of his first year and before he has had much general chemistry, at least in too many schools. Such an arrangement is very likely to result in a student getting only a superficial knowledge of the chemistry of digestion and metabolism. The chapter on electro-physiology is introduced between those on the muscular system and the nervous system. This arrangement, too, has its advantages and disadvantages. The logical position of the chapter on electro-physiology is maintained by Professor Ott, and is to be commended in the interests of clear teaching and of clear understanding on the part of the student. From the standpoint, however, of the experimental presentation of physiology, it is practically universal to present muscle nerve physiology first in physiologic laboratory texts; the technic used in this field of physiology is simple, and practically makes the foundation for that which is to follow in the work on circulation, respiration and nervous systems.

Laboratory Manual of Physiological and Pathological Chemistry, for Students in Medicine. By Dr. E. Salkowski. Professor in the University and Director of the Chemical Laboratory of the Pathological Institute. Berlin. Authorized Translation from the Second Revised and Enlarged German Edition. By W. R. Orndorff. A.B., Ph.D., Professor of Organic and Physiological Chemistry in Cornell University. With 10 Figures and a Colored Plate of Absorption Spectra. First Edition. First Thousand. Cloth. Pp. 263. Price, $2.50. New York: John Wiley & Sons. 1904.

This manual is a clear and concise summary of the reactions and tests that have been found most practically useful for the medical student, both before and after graduation. Chapter I on the "Examination of Milk" takes up in order the following subjects: General properties of milk, separation of milk into its constituents, precipitation with magnesium sulphate, action of rennin on milk, preparation of lactic acid. Each of the other chapters is subdivided in a similar way, making the whole book admirably clear and easy for reference. Methods that are of little practical value, or that have been superseded by better ones, are left out. Only the cream of the subject is retained. The chapters on the "Examination of Muscular Tissue" and on "Gastric Digestion" are particularly interesting in view of the growing importance of dietetics as a factor in the treatment of diseases of the digestive tract. Footnotes have been added by the translator to keep the book up to the times. For example, the alcoholic solution of dimethylamidoazobenzol, which is practically the only reagent now used for the detection of free hydrochloric acid in stomach contents, is not referred to in the text, but is mentioned in a footnote. No reference is made to the quantitative determination of free hydrochloric acid with this reagent and a decinormal solution of caustic soda; a test with which every one who undertakes to treat diseases of the stomach ought to be familiar. Some weakness appears also in regard to the estimation of the digestive power of fluids. Either Mett's or Hammerschlag's or Bettman's method is preferable to the one given in the text. After an excellent chapter on examination of the blood the author discusses the examination of pathologic transudates, cystic fluids. Then follow chapters on saliva and salivary digestion, the pancreas, bile, biliary calculi, urine, urinary calculi, the liver, bone, adipose tissue, yolk and white of the egg, and the products of the putrefaction of proteids. For the student who wishes to pursue the subject still further are added ten chapters on quantitative analysis. In these are discussed with sufficient fullness for practical purposes the analysis of meat, milk and bread. These processes are not usually given in a brief manual of this kind, and their presence adds very materially to the value of the book. The quantitative examination of urine, feces and blood, the determination of hydrochloric acid, or glycogen, and of the rate of digestion, complete the text. In the appendices are placed a list of reagents, tables of specific gravities, and a list of international atomic weights.

LECTURES, CHIEFLY CLINICAL AND PRACTICAL, ON DISEASES OF THE LUNGS AND THE HEART. By James Alexander Lindsay, M D., F.R.C.P. (Lond.), M.A., Professor of Medicine, Queen's College, Belfast. Cloth. Pp. 447. Price, $3.50 net. New York: Wm. Wood & Co. 1904.

This book contains twenty-one lectures which the author delivered at the Royal Victoria Hospital of Belfast during the past fifteen years. They deal with problems and difficulties which confront the physician in the diagnosis, prognosis and treatment of the common diseases of the chest. The first thirteen lectures are devoted to the lungs and pleura, and of these the first three are introductory and concern methods of physical examination and anamnesis. The last eight lectures deal with cardiac disease, chiefly valvular, the first three being devoted to methods of examining the heart and blood vessels. The lectures are eminently practical, the style is clear and terse, but it strikes one as rather peculiar and disappointing not to come across any exposition of the pathology of the diseases considered and only passing allusions to etiology. For this reason the work commends itself to practitioners and not to students of medicine, unless it be assumed that senior students are so familiar with causation and pathology as to need no further exposition of these subjects. The value of the book would be greatly enhanced had the author introduced a brief discussion of these important phases of thoracic disease. It is worthy of note that Professor Lindsay places himself squarely with those who regard the crepitant râle of pneumonia as a pleuritic exudation râle, the view first advocated we believe by Leming of New York. Although granting that it is difficult if not impossible to conceive of this râle as caused by the entrance of air into air vesicles, still we think the arguments adduced by Lindsay and other supporters of the pleuritic origin of the sound are not convincing. We have heard râles undoubtedly generated by pleural friction, which closely resembled the true crepitus of pneumonia, but there was a perceptible difference which, together with the clinical fact that the true pneumonic râle occurs only at the beginning and close of pneumonia and not when consolidation is complete, seems to us strong evidence in favor of the intrabronchial origin of this adventitious sound. We were greatly pleased with what the author says regarding the importance of the early recognition of pulmonary tuberculosis and its bearing on prognosis and treatment. What he says concerning prognosis in this disease is especially good, and it is a matter for rejoicing that so able and influential a physician as Dr. Lindsay emphasizes the value of the open-air treatment of tuberculosis at home as against drug therapy and the sending of consumptives away from home. The inculcation of such views is one of the advances of the day and one of the greatest duties of the clinical teacher of internal medicine. The lectures on cardiac disorders are commendable and furnish additional proof of the practical utilitarian views of this teacher. On the whole the volume will prove a desirable addition to the working library of the general practitioner, who is already provided with treatises which deal with those aspects of thoracic disease not considered in this volume.

State Boards of Registration.

COMING EXAMINATIONS.

Ohio State Board of Medical Registration and Examination, Columbus, June 13-15. Secretary, Frank Winders, M.D., State House, Columbus.

Michigan State Board of Registration in Medicine, Lansing, June 14 Secretary, B. D. Harison, M.D., Sault Ste. Marie.

Board of Medical Examiners for the State of Texas, Houston, June 15, Secretary, M. M. Smith, M.D., Austin.

Board of Medical Examiners of Maryland, Lehman's Hall, Baltimore, June 15-18. Secretary, J. McP. Scott, Hagerstown.

Missouri State Board of Health, Kansas City, June 20-22. Secretary, W. F. Morrow, M.D., Kansas City.

Medical Society of Delaware, Dover, and the Homeopathic Medical Society of Delaware State and Peninsula, Wilmington, June 21. Secretary Medical Council, P. W. Tomlinson, M.D., Wilmington.

New Jersey State Board of Medical Examiners, June 21-22, Trenton. Secretary, E. L. B. Godfrey, M.D., Camden.

Medical Examining Board of Virginia, June 21-24, Richmond. Secretary, R. S. Martin, M.D., Stuart.

State Board of Medical Examiners of South Carolina, State House, Columbia, June 28. Secretary, W. M. Lester, Columbia.

State Medical Society of Pennsylvania, June 28 30, Philadelphia and Pittsburg. Secretary, Isaac B. Brown, M.D., Harrisburg.

Territorial Medical Examining Board of Oklahoma, Guthrie, June 29. Secretary, E. E. Cowdrick, M.D., Enid.

Arizona Board of Medical Examiners, July 4, Phoenix. Secretary, William Duffield, M.D., Phoenix.

Utah State Board of Medical Examiners, July 4, Salt Lake City. Secretary, R. W. Fisher, M.D., Salt Lake City.

North Dakota State Examining Board, July 5, Grand Forks. Secretary, H. M. Wheeler, M.D., Grand Forks.

Board of Medical Examiners of the State of Oregon, July 5-7, Portland. Secretary, Byron E. Miller, M.D., the "Dakum," Portland.

Washington State Board of Medical Examiners, July 5-7, Spokane, Secretary, P. B. Sweringen, Tacoma.

Rhode Island State Board of Health, July 7, State House, Providence. Secretary, Gardner T. Swarts, M.D., Providence.

West Virginia State Board of Health, July 12-14, Point Pleasant. Secretary, Hugh A. Barbee, Point Pleasant.

Indiana State Board of Medical Registration and Examination, July 12, State House, Indianapolis. Secretary, W. T. Gott, M D., Crawfordsville.

Arkansas State Medical Board of Examiners, July 12, Little Rock. Secretary, J. P. Runyan, M.D., Little Rock.

Connecticut Medical Examining Board, July 12-13, City Hall, New Haven. Secretary, Charles A. Tuttle, M.D., New Haven.

Wisconsin State Medical Board, July 12, Madison. Secretary, F. A. Forsbeck, M.D., Milwaukee.

Board of Medical Examiners of the State of California, July 12, Los Angeles. Secretary, George G. Gere, M.D., San Francisco.

Maine Board of Registration of Medicine, July 12 and 13, City Building, Portland. Secretary, A. K. P. Meserve, M.D., Portland.

Vermont State Board of Medical Censors, July 13-14, Y. M C. A. Building, Burlington. Secretary, S. W. Hammond, Rutland.

South Dakota Board of Medical Examiners, July 13 and 14, Watertown. Secretary, H. E. McNutt, M.D., Aberdeen.

Board of Medical Supervisors of the District of Columbia, July 14, Washington. Secretary, Wm. C. Woodward, M.D, Health Department, Washington.

Rhode Island April Report.—Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports that at the written examination held at Providence, April 7-8, 1904, 70 questions were asked on 7 subjects, and a percentage of 75 was required. All of the seven who were examined passed.

PASSED.

College.	Year Grad.	Per Cent.
University of Vermont	(1903)	76.1
University of Pennsylvania	(1902)	83.8
Harvard University (1897) 78.6,	(1902)	86.1
College of Physicians and Surgeons, Baltimore	(1902)	75.0
Yale University	(1901)	84.1
Boston University	(1900)	77.9

Idaho April Report.—Dr. Robert L. Nourse, secretary of the Idaho State Board of Medical Examiners, reports that at the written examination held at Boise City, April 5 to 8, 1904, 110 questions were asked on 11 subjects and a percentage of 75 was required. Of the 19 examined 9 passed and 10 failed.

PASSED.

College.	Year Grad.	Per Cent.
Rush Medical College	(1903)	78.8
Long Island College Hospital	(1894)	82.0
University of Michigan	(1882)	83.8

Utah April Report.—Dr. R. W. Fisher, secretary of the Utah State Board of Medical Examiners, reports that at the written examination held at Salt Lake City, April 4, 1904, 125 questions were asked on 20 subjects and a percentage of 75 was required. All of the 7 who were examined passed.

PASSED.

College.	Year Grad.	Per Cent.
Medico-Chirurgical College, Philadelphia	(1902)	85.7, 86.8
Gross Medical College, Denver	(1900)	84.2
Northwestern University, Chicago	(1902)	84.3
Washington University, St. Louis	(1899)	82.3
Illinois Medical College, Chicago	(1904)	90.0
Kentucky School of Medicine	(1903)	82.5

The board has increased the number of subjects so that the requirements are now: Diploma and examination with an average of 75 per cent. on the following subjects: Bacteriology, histology, medical jurisprudence, practice and pathology, pediatrics, chemistry, materia medica, therapeutics, obstetrics and gynecology, diseases of skin, anatomy, surgery, eye, ear nose and throat, hygiene, physiology.

Louisiana May Report.—Dr. Felix A. Larue, secretary of the Louisiana State Board of Medical Examiners, reports that at the written examination held at New Orleans, May 6 and 7, 1904, 50 questions were asked on 10 subjects, and a percentage of 75 was required. Of the 115 candidates, 103 passed and 12 failed.

Minnesota April Questions.—The Minnesota State Board of Medical Examiners, at the April, 1904, session, asked the following questions:

HISTOLOGY AND PATHOLOGY.

1. Give pathology of kidney in chronic interstitial nephritis. 2. How would you make a Widal's test? What is its value in diagnosis? 3. Name varieties of tapeworm found in man, and give usual source of infection of each. 4. Name the different varieties of leucocytes and give the proportion of each in normal blood. 5. Explain the difference between active and passive congestion. 6. How would you make a bacteriologic diagnosis of diphtheria? 7. What are the vital manifestations of a cell? 8. How does a peptic gland differ in structure from a pyloric gland? 9. Describe a nerve cell. What is meant by a bipolar cell? 10. What form of epithelium occurs in the following organs: Lungs, urinary bladder, stomach, ureters, oviduct, vas deferens, cornea?

MATERIA MEDICA AND THERAPEUTICS.

1. What is the strength in arsenic of Fowler's solution? Of opium in paregoric? Of ipecac and of opium in Dover's powder? 2. Prescribe salicylate of soda for an adult at the beginning of a sharp attack of acute articular rheumatism. 3. Name the three principle antipyretics of the coal-tar series and the adult dose of each. 4. Write a formula for a laxative pill containing aloes and podophyllum for an adult. 5. Criticise this prescription:

℞. Zinci sulphatis.
Plumbi acetatis, of each........................gr. xxx
Aquæ rosæ ....℥vj
M.:

6. How would you use antitoxin in the early stage of a severe attack of diphtheria in a child 6 years old? 7. Prescribe an ointment for a case of scabies. 8. Give the average adult dose of each of the following: extract of nux vomica; bichlorid of mercury; oil of sandal wood; extract of hyoscyamus; tincture of opium. 9. Prescribe iodid of potash for an adult suffering from a syphilitic ulcer of the leg. 10. What precautions are necessary in prescribing tincture of the chlorid of iron? Why?

HOMEOPATHIC MATERIA MEDICA.

1. Differentiate between aconite, belladonna and arsenic in fevers. 2. Give *prominent symptoms of baptisia, rhus* and *bry*, which indicate them in typhoid fever. 3. Give characteristic symptoms of lycopodium. 4. Give characteristic symptoms of digitalis cactus and spigelia in heart affections. 5. Give a picture of child in whom calcarea carb. is indicated. 6. Give prominent symptoms of gels. 7. Name four remedies having special action on the female generative organs. 8. Give four remedies of use in diarrhea with their most characteristic differential symptoms. 9. Name three remedies of service in follicular tonsillitis. 10. What conditions indicate hypericum arnica; rhus tox. in injuries?

ECLECTIC MATERIA MEDICA.

1. Give the use of lobelia in eclampsia; of veratrum; and dose of each. 2. Give the indications for the use of bryonia and rhus tox. What are their physiologic actions? 3. What is acetanilid? Give physiologic action. 4. Name some of the later alkaloids of opium and the dose of each. 5. Give use and dose of Jamaica dog-wood; chloral hydrate; trional; sulphonal; cannabis indica. 6. Give physiologic action of ergot; digitalis; gelsemium. 7. What are the specific indications for chamomile; nux vomica; ipecac; hydrastis? 8. Name three reliable tonics; three stimulants; three sedatives. 9. What are the medical properties of turpentine, and how would you give it? 10. Name some conditions calling for collinsonia; sanguinaria and phytolacca.

EYE AND EAR.

1. Otitis media: Pathology, symptoms, treatment. 2. Primary glaucoma. Symptomatology, treatment. 3. Surgical removal of eye. When? How? 4. Discuss. (*a*) Care of eyes of new born. (*b*) Care of eyes of *school children*. 5. What *eye* and ear *complications* would you be on the lookout for, and what prophylactic measures would you accordingly take in the following diseases: (*a*) Measles; (*b*) scarlet fever; (*c*) diphtheria.

SURGERY.

1. Give diagnosis and treatment of hip-joint disease. 2. Diagnosis and treatment of gastric ulcer. 3. Give treatment for tubercular cervical glands. 4. Give treatment of hemorrhoids. 5. Diagnosis and treatment for strangulated inguinal hernia. 6. Treatment for gunshot wound of abdomen where bowel has been penetrated. 7. Diagnosis and treatment for compound fracture of femur. 8. Treatment for fractured clavicle. 9. Give treatment for dislocation of knee joint. 10. Give treatment for lacerated and contused wounds in general.

MEDICAL JURISPRUDENCE.

1. Before beginning an autopsy in a medicolegal case, what points are to be noted? 2 State the principal differences between the adult male and the adult female skeleton. From the skeleton alone can a positive opinion be formed as to the sex? 3. What is the greatest possible duration of a pregnancy that may result in the birth of a living child? 4. What conditions influence the time of appearance of rigor mortis? 5. What is the minimum fatal dose in an adult of arsenious acid? Of sulphate of morphia?

DISEASES OF WOMEN.

1. Movable kidney: Define and give etiology, symptomatology, prognosis and treatment. 2. Neoplasms of the ovaries: Give the two classes and the varieties in each class. 3. Describe Emmet's operation for restoration of the pelvic floor in incomplete laceration of the perineum. 4. Cysts of Bartholin's gland. Etiology, symptomatology and treatment. 5. Pudendal hematocele, causes, symptoms, treatment.

DISEASES OF CHILDREN.

1. Scorbutus: Etiology, lesions, symptomatology and treatment. 2. Chronic intestinal indigestion: Etiology, symptomatology, diagnosis and treatment. 3. Anuria: Etiology, symptomatology and treatment. 4. Acute diffuse nephritis: Etiology symptomatology, diagnosis and treatment. 5. Epilepsy: Symptoms and treatment.

ANATOMY.

1. Describe the atlas. 2. Into what classes are articulations divided? 3. Describe and give origin and insertion of the pronator radii teres muscle. 4. Describe the abdominal aorta, giving its use and termination. 5. Name the principal veins of the head and neck. 6. Give characteristics of lymphatics; where are they not found? 7. Name the membranes of the brain. Give brief description of each. 8. Give brief description of the spinal cord. Give only its gross anatomy. 9. Name the openings into the pharynx. 10. Give gross anatomy of the liver.

PHYSIOLOGY.

1. Name one property common to all blood leucocytes and give some of their physiologic uses. 2. What is lymph and its mode of reaching the lymphatic vessels and glands, and, finally, the venous circulation? 3. Tell something concerning cerebral localization, describing any three local centers. 4. Give origin and function of anterior and posterior roots of spinal nerves. 5. What is the composition, reaction and function of the pancreatic juice? 6. Give normal constituents of arterial blood, and the process by which venous is converted into arterial blood, and the physiologic necessity therefor. 7. Give nature of function performed by kidney and detail with some minuteness the method of its performance. 8. What is the physiologic difference between striated and non-striated muscular tissue, giving some examples of each. 9. Describe the portal circulation. 10. Give normal constituents of urine, and amount voided (approximately, in ounces) in 24 hours.

THEORY AND PRACTICE.

1. Give physical signs of pleuritic effusion. 2. Describe sonorous, sibilant, crepitant and mucous râles. 3. Give causes and diagnosis of gastric ulcer. 4. Give etiology and symptoms of cerebral embolism. 5. Name the chronic diseases of the liver. 6. What do you understand by enteroptosis, and what are the common pathologic conditions involved? 7. Name six chronic diseases most likely to be associated with a daily rise of temperature. 8. What is the difference. between intermittent and remittent fever? 9. Give differential diagnosis between chronic parenchymatous nephritis and chronic interstitial nephritis. 10 Give the normal location of the apex beat of the heart, and give diagnostic significance of its various displacements.

CHEMISTRY, URINALYSIS AND TOXICOLOGY.

1. Define base, salt, acid. 2. Hydrochloric acid, composition, physical properties. 3. Mercury: Physical properties, preparations. 4. Arsenical poisoning: Symptoms. treatment, postmortem findings. 5. Urine analysis: (*a*) Name causes of high specific gravity. (*b*) Name most important constituents of normal urine.

OBSTETRICS.

1. What are the anatomic differences between the male and female pelvis? Give diameters of superior strait of female pelvis. 2. How do you differentiate a vertex from a breech presentation? 3. What are the dangers of a breech presentation? Describe your method of management. 4. What is eclampsia? Causes. Treatment. 5 What is the significance of ante-partum hemorrhage? Give treat ment. 6. How do you manage a face or brow presentation? 7. What means do you employ to guard against rupture of the perineum? Treatment if ruptured? 8. What other causes beside a noncontraction of uterus may give hemorrhage following labor? 9. What is "Ophthalmia"? Give treatment. preventive and curative. 10. On which side do you place the new-born babe? Is there any scientific reason for a choice of sides.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Acute Bronchitis.

In considering the treatment of bronchitis, according to *Canad. Prac. and Rev.*, it is necessary to bear in mind the etiology of the disease, such as irritating vapors, a cold east wind, Bright's disease, cardiac lesions or some acute infectious disease.

The treatment necessarily varies with the stages. When there is soreness in the chest and scanty sputa, pain on coughing, the bronchial tubes inflamed and congested, warm moist air has a soothing effect on the membrane and counteracts the dryness. A steam kettle and a tent bed often give relief. Warm liquid food should be given, as swallowing hot fluids has a reflex act on the bronchi and aids the expectoration by increasing the flow of mucus. Hot poultices or fomentations to the chest and back make the patient more comfortable. In other cases stimulating liniments, such as those containing turpentine and acetic acid, may be preferred. Internally a mixture similar to the following may be given:

℞.	Ammon. carb.			
	Pot. iodidi, āā	gr. iii		20
	Sol. ammon. acetat	ʒii	8	
	Aq. camphoræ	℥i	30	

M. Sig.: The entire amount to be taken once in four hours; or:

℞.	Vini ipecac.			
	Tinct. scillæ, āā	m. x		65
	Spts. etheris nit.	ʒss	2	
	Aq. chloroformi	℥i	30	

M. Sig.: At one dose and repeat every four hours.

The effect of the iodid is to thin the mucous secretion and render the act of expectorating less difficult. If it is desired to add potassium iodid to the latter mixture it is necessary to add an alkali, as ammonium carbonate, to neutralize the slight acidity of the nitrous ether.

In aged individuals there is frequently a tendency to heart failure, so that alcohol or strychnia may be in demand or the following mixture may be of service in such cases:

℞.	Spts. etheris sulph.		
	Spts. ammon. arom., āā	gtt. xv	1
	Syr. aurantii	ʒss	2
	Aq. camphoræ	℥i	30

M. Sig.: One such dose every four hours.

If necessary a few drops of the tincture of digitalis may be added to the foregoing combination.

A brisk purgative is often necessary as the initial treatment in this trouble, which may be Carlsbad salts, Seidlitz powder or calomel, given in one large dose. Sedatives must be given with care. During convalescence, after the cough has loosened up, these stimulating expectorants may be discontinued, and in their stead an acid tonic may be given, such as the following:

℞.	Acidi nitrici dil.	gtt. x		65
	Tinct. nucis vom.	gtt. v		30
	Spts. chloroformi	gtt. x		65
	Infus. gent. co.	℥i	30	

M. Sig.: One such dose to be taken after each meal; or:

℞.	Tinct. cinchonæ	m. xx	1	30
	Acidi nitrici dil.	m. x		65
	Syr. aurantii	ʒi	4	
	Aq. chloroformi	℥i	30	

M. Sig.: One such dose after each meal.

In some cases quinin is indicated, in others some preparation of iron. In children a compound syrup of the phosphate of iron is useful. Malt extract and cod-liver oil are also of service.

Antimony is sometimes of service in cases of acute bronchitis, according to Yeo, especially if administered early in the disease, when the bronchial mucous membrane is dry and tumid, before the secretion has become abundant and when the skin is hot and dry and the pulse hard. It should be given, according to the author, in small and frequently repeated doses, combined with other diaphoretics. Ten to twenty minims (.65-1.30) of the wine of antimony may be given to adults, and five to ten minims (.30-.65) to children. It can be combined with other diuretics as follows:

℞.	Vini antimonialis	ʒii	8
	Spts. etheris nitrosi	ʒiv	15
	Liq. ammon. acetatis	℥ii	60
	Tinct. camphoræ co.	ʒii	8
	Aquæ q. s. ad	℥viii	240

M. Ft. mistura. Sig.: Two tablespoonfuls every three or four hours.

The following combination is also recommended by this author as a suitable combination in acute bronchitis:

℞.	Infusi senegæ	℥iv	120
	Ammon. carb.	gr. xxx	2
	Tinct. scillæ	m. lxxx	5
	Spts. chloroformi	ʒii	8
	Aquæ q. s. ad	℥viii	240

M. Sig.: Two tablespoonfuls every four or five hours.

In debilitated individuals, when the earlier stages are not encountered, the following is recommended:

℞.	Ammon. carb.	gr. xl	2	65
	Vini ipecac.	m. xl	2	65
	Tinct. cinchonæ	ʒiv	15	
	Aquæ chloroformi q. s. ad	℥viii	240	

M. Ft. mistura. Sig.: Two tablespoonfuls every four hours.

In advanced rheumatic or gouty cases when the expectoration is tenacious and difficult to expel, the potassium iodid is indicated, combined as follows:

℞.	Pot. iodidi	gr. xxxv	2	30
	Sod. chloridi	ʒi	4	
	Ammon. carb.	ʒss	2	
	Sodii bicarb.	gr. xl	1	65
	Tinct. senegæ	ʒiii	12	
	Aq. chloroformi q. s. ad	℥iv	120	

M. Ft. mistura. Sig.: One or two tablespoonfuls four times daily.

The following combinations are recommended by *Merck's Report* as of service in bronchitis:

℞.	Syr. picis liquidæ	℥i	30
	Syr. pruni virg.		
	Syr. tolutani, āā	℥iss	45

M. Sig.: One teaspoonful every three hours; or:

℞.	Ext. marubii flu. (horehound)	℥ss	15
	Syr. tolutani	℥i	30
	Syr. picis liq.	ʒvi	24
	Syr. glycyrrhizæ	ʒvi	24

M. Sig.: One teaspoonful every three hours.

Arteriosclerosis.

The following combination is recommended by Huchard, in *Clin. Ther.*, in the treatment of arteriosclerosis:

℞.	Sodii iodidi	ʒi	4
	Sparteinæ sulph.	gr. xv	1
	Pulv. glycyrrhizæ q. s.		

M. Ft. cap. No. xl. Sig.: Four to six daily.

Aneurism.

The following combination containing iodids and bromid is recommended in the treatment of aneurism:

℞.	Pot. iodidi		
	Sodii bromidi, āā	ʒii	8
	Syr. aurantii flor.	ʒiv	15
	Aquæ q. s. ad	℥vi	180

M. One tablespoonful three times daily.

For the cough in aneurism the following is advised:

℞.	Morphinæ hydrochlor.	gr. i		06
	Acidi hydrochlor. dil.	m. v		30
	Acidi hydrocyanici dil.	ʒss	2	
	Syr. scillæ			
	Aquæ, āā	℥i	30	

M. Sig.: One teaspoonful as necessary; or:

℞.	Syr. scillæ	ʒii	8
	Spts. lavendulæ co.		
	Tinct. opii camph.		
	Syr. simplicis, āā	ʒiv	15
	Aq. menth. pip.	℥ii	60

M. Sig.: One tablespoonful every three hours.

To relieve the pain and restlessness the following:

℞.	Morphinæ hydrochlor.	gr. 1/4-1/3		015-.020
	Spts. etheris sulph.	ʒss	2	
	Aq. menth. pip. q. s. ad	℥i	30	

M. Sig.: At one dose and repeated according to instructions.

And to relieve the neuralgia, which is usually a constant symptom in aneurism, the following liniment is recommended:

℞.	Ext. belladonnæ	ʒii	8
	Ext. opii	ʒi	4
	Spts. vini rect.	ʒss	2
	Glycerini	℥ss	15

M. Ft. linimentum. Sig.: To be applied to the painful area.

Gastric Ulcer.

Woodville, in *Ther. Rev.*, recommends bismuth subnitrate, as originated by Fleiner, in large doses in the treatment of gastric ulcer. Fleiner administered from 45 to 120 (3.-8.) grains through the stomach tube. Woodville does not recommend the stomach tube on account of the danger of perforation. His treatment consists in a diet of small quantities of milk and a little albumin ordered at intervals of three or four hours. If other nourishment is needed it should be given per rectum. He gives the bismuth subnitrate suspended in one glass of milk three times a day, and continues the treatment for three weeks without interruption. Bismuth thus given in this manner arrests the vomiting, and forms a protective coating over the ulcer, and in this way permits the process of repair to go without interruption. Cathartics should never be given by the mouth. The bowels should be kept open by enemas. Toxic symptoms do not occur.

Medicolegal.

Damages for Scalds.—The Court of Civil Appeals of Texas says, in Houston & Texas Central Railroad Company vs. Bulger, a personal injury case brought by the latter, that the evidence showed that the plaintiff, a boy about 13 years of age, was severely scalded on both legs, on one extending from the upper third of the thigh to the heel; that he suffered the most intense pain for over three months; that the burns did not permanently heal until the next December following the date of infliction, which was March 8; that the skin proper on the right leg, and in patches on the left, was destroyed; that, in healing, the scars had contracted on the blood-vessels, and the pressure interfered with the circulation of the blood, and would probably cause varicose veins and trouble in after life. Under these circumstances, the court does not think that it could be said that a verdict for $4,000 damages was excessive.

Proper Expert Evidence of Capacity in Rape Case.—The Supreme Court of Kansas says that, in the case of State vs. Walke, a prosecution for statutory rape, the accused was a man 68 years old. His wife testified that he had lost virility to the extent that he was incapable of having sexual commerce with a woman. This she knew from her intimate relations with him. On rebuttal physicians were called, and permitted to testify as experts that a man of that age, having lost sexual desire as to his wife, might still have such desire and ability to consummate it on other and younger women. The court finds no error here. The question involved, it says, was not one so clearly falling within the range of common experience and observation as to exclude expert evidence in proof of the same, nor that the jury might surely assume its truth without the evidence of an expert. Expert evidence is admissible in proof of matters not clearly falling within the range of common experience or observation.

Liability for Expenses to Check Contagious Diseases.—The Supreme Court of Minnesota holds, in the case of Comstock vs. Board of Commissioners of Le Seuer County, that Section 29, Chapter 132, page 185, of the General Laws of that state of 1883, making towns, boroughs, and villages liable in the first instance for all expenses incurred by their boards of health, acting under the provisions of that statute, in efforts to control and prevent the spread of infectious and contagious diseases, was amended and repealed by subsequent legislation, so that in 1901 the county in which the town, borough, or village is situated was solely liable for all such expenses. The town, borough or village was not during that year liable for such expenses, primarily or otherwise. It says, further, that it is probable that the primary liability of towns and villages is restored by the act of 1902, but that it does not attempt to construe that act in this case, its provisions having no application here on account of its having been passed after the transaction involved in this case was closed.

Physician Not Competent Witness to Sustain Certificate.—The Supreme Court of New York, trial term, Chenango County, says that in the case of Becker vs. Metropolitan Life Insurance Company, the company claimed that the insured had an attack of cerebral apoplexy and was treated therefor prior to the time that he applied for insurance, but that the facts were concealed from the company's agent at the time of making the application for insurance. The plaintiff, who was seeking to recover the insurance, put in evidence the application, the policy, and the proofs of death, which showed, on their face, that the plaintiff was not entitled to recover. The physician's certificate of death showed the previous illness, on which, with a statement in the plaintiff's affidavits, the company sought to make its defense. The court holds that the plaintiff had the right to show that the statements in the certificate were not true; and that, having explained and shown the untruthfulness of the physician's certificate, the physician had no right to take the stand for the purpose of sustaining the certificate and contradicting the beneficiary, under the statute with regard to privileged communications, he having acquired his information in the capacity of an attending physician.

Opinion Evidence as to Cause of Physical Condition.—The Supreme Court of Wisconsin says, in the personal injury case of Lyon vs. City of Grand Rapids, that a question was allowed to a physician, called to give opinion evidence, as to what caused a particular diseased condition of the plaintiff, which he testified she was suffering from, basing such opinion on the assumption that she had testified truthfully, and what he had seen of her from time to time, including that discovered on his examination of her person as her physician. The question was objected to as incompetent. It was not controverted, but that it was permissible for the expert to give opinion evidence as regards whether such condition was caused by violence of some kind applied to the plaintiff's person, or by some other immediate producing cause not going to the circumstance which set such cause in motion. The books are full of instances of opinion evidence of that character. Whether an injury of the kind in question is sufficient to produce the particular effects alleged to have been caused thereby is a proper subject for expert evidence. For the purpose of interrogating an expert as to whether a particular condition of the human system found to exist at a particular time is referable to violence, blood poisoning, or some other immediate producing cause, the form of the question is often that adopted in this case. "What, in your opinion, is the cause of the condition which you discovered?" or, on the hypothesis that the physical condition of the person is as stated in the question, the expert is commonly asked to give his opinion as to the cause thereof, meaning thereby, generally, the immediate cause. That is about as far as opinion evidence should be permitted to go other than under exceptional circumstances, which strictly exclude any other producing cause than the particular one involved in the controversy. In such cases questions have been permitted which seem to invade the salutary rule that the expert is not to be permitted to usurp the functions of the jury by passing on issues to be submitted to them. In Maitland v. Gilbert P. Co., 97 Wis., 476, and Daly v. Milwaukee, 103 Wis., 588, it was said, in effect, that so long as the opinion of the expert is based on undisputed facts or an assumed state of facts warranted by the evidence in some aspect thereof, and is kept within the field of scientific knowledge, the question calling therefor is not necessarily objectionable because the tendency of the answer is to pass on some ultimate question to be submitted to the jury for final solution. However, that is somewhat dangerous ground. The safer way is to go no further than to show by the opinion evidence that the particular circumstances proved or assumed are a sufficient producing cause for the effect complained of. No definite rule can be given accurately defining the limits to which such questions can go. The discretionary authority of the trial judge in that field is somewhat broad. It must necessarily be exercised with regard to the particular facts of the case in hand. Any attempt to give a rule more definite than the one commonly given, that is, that the opinion evidence must not be permitted to extend to the merits of the controversy, passing on the very question, or one of them, to be submitted to the jury, or to go outside the field of scientific knowledge, would not improve it. Of course, when that rule is analyzed, as will be discovered by examining the opinion in Maitland v. Gilbert P. Co., the term, "pass on the controversy to be submitted to the jury," means pass on some disputed evidentiary matter on which the final result in whole or in part depends, or pass on some matter not within the scope of scientific knowledge. In attempting to harmonize the adjudications on the subject found in the books, one soon discovers that courts have applied the principles stated so variously that the function of expert testimony and that of the jury many times appear to so blend that the best experts in the science of the law can not discover where the one ends and the other begins. It would seem that opinion evidence should be sufficiently restrained that such will not be the case, and it is believed that as regards the cases decided in this court that has, generally speaking, been done. It is easy to understand that opinion evidence should be kept within the field of scientific knowledge; also that whether the particular conditions of the human system might be produced by a particular physical disturbance, or whether it was or might be produced by a particular immediate cause, is within such field; but not, generally speaking, easy to see that whether a particular physical disturbance as to one person, attributable to actionable fault of another, is the cause of the bodily condition of such person, the immediate cause of which is to be sought for by scientific knowledge.

2 Experimental Pancreatitis Considered in Its Relation to the Acute Forms of Pancreatitis in Man. Richard M. Pearce.
3 Acute Anterior Poliomyelitis in Adults, with Report of a Case in which There Was Also a Peripheral Facial Palsy and Paradoxic Pupils Complicated with Hippus. Alfred Gordon.
4 *Neuritis as a Complication of Some Portion of the Childbearing Process. William R. Nicholson.
5 Clinical Report of a Case of Lithogenous Icterus. Byron Robinson.
6 Posterior Gastroenterostomy, with Entero-enterostomy: a Study of Conditions Found at Autopsy. W. L. Wallace.
7 Observations on the Duty of the Physician to His Patient Through the Surgeon. Henry Sewall.
8 Santa Cruz Mountains of Jamaica, West Indies, for the Tuberculous. Logan Russell and Leslie Alexander.

1. **Empyema.**—Willard remarks that the condition is very often unrecognized, and gives certain diagnostic points that are of value. His general summary of conclusions is stated as follows:

1. Early diagnosis of pleurisy and early operations are the prime elements in the avoidance of empyema. The general practitioner is the one who needs to be on the alert.
2. A test for fluid should be made with the aspirating needle, not a hypodermic, as the latter is too small and short. Liquid, if present, should be immediately withdrawn; if purulent, further operation within a day or two is advisable as soon as the lung expands and the heart moves toward its normal position. Aspiration should be limited to diagnostic purposes, to the withdrawal of serum, and as a preliminary operation in empyema.
3. In all cases of pyothorax, free drainage, not aspiration, should be the rule. The larger the openings the quicker will cure be effected. Resection of ribs is imperative for exploration by the finger and for removal of fibrinous masses.
4. Washings are counterindicated, except in fetor, and even then more perfect drainage is indicated rather than irrigation.
5. In old chronic cases with contracted lung and degenerated pleura, more or less excision of the chest wall and pleura should be performed, even to the excision of the entire extent of all the ribs.
6. Even in tuberculous empyema, benefit is derived from thorough drainage.

4. **Neuritis from Childbearing.**—Nicholson calls attention to the occurrence of neuritis after delivery, and reports two cases, discussing the causes of the condition, such as sepsis, pressure, etc., and points out that symptomatology may vary widely. The time of onset may be in the latter part of the pregnancy, during labor or at any time for several weeks afterward. The symptoms vary from transient pain similar to rheumatism to a symptom-complex resembling acute ascending paralysis or myelitis. The usual type is intermediate between these extremes. The nerves involved in the milder cases are the median and ulnar, or, if the leg is affected, the sciatic, gluteal and especially the external popliteal causing the presence of so-called foot-drop. In very severe cases every portion of the body is involved. He thinks that the milder cases often pass undiagnosed, the patient having been hardly aware of the symptoms that existed.

9 The Construction of the Valvular Part of the Aorta and the Significance of Its Elastic and Collagenous Tissue. Fritz Schwyzer.
10 *Examination of the Bladder in 20 Cases of Ventral Suspension. Swithin Chandler.
11 *The Surgery of Nephritis. (Concluded.) George M. Edebohls.
12 *A New Method to Facilitate Operations in the Mouth, for the Purpose of Minimizing the Danger of Aspiration of Blood During General Anesthesia. Alfred W. Herzog.

13 What Should the General Practitioner Know of Ophthalmology? H. H. Seabrook.

10. **Ventral Suspension.**—Chandler reports the result of an examination of twenty cases of ventrosuspension to demonstrate the incorrectness of the idea of the necessity of bladder troubles after operation. While he says that his series of cases is too small to admit of positive conclusions, they are sufficient, he thinks, to warrant him in the following deductions:

1. In all cases requiring ventral suspension the bladder should be thoroughly examined by a cystoscope.
2. In no cases reported among this number was there any trouble with frequent micturition after the operation of ventral suspension, except where there was some evidence found which would cause such disturbance.
3. The new position of the bladder after ventral suspension aided and relieved, rather than caused, frequent micturition.
4. The said operation may have caused this relief by removing pressure from the neck of the bladder, which pressure undoubtedly helps to cause frequent micturition.
5. The left ureter opening and surrounding parts were often affected, but the cases are too few to state positively why this existed in these cases.
6. Immediate and prompt treatment saves much suffering and adds much to the surgeon's reputation and to that of the operation.
7. By examining the bladder and surrounding parts we may find cases in which suffering may be relieved, when for some reason an operation for uterine disease can not be performed.
8. To make such examination eliminates errors, and is more scientific; and the more exact we become the firmer ground we tread.

11. **Surgery of the Kidney.**—Edebohls points out the indications for renal decapsulation, as well as the contraindications as he understands them. The three conditions are: 1, A clear and unequivocal establishment of the presence of chronic Bright's disease; 2, absence in most cases of contraindications to any operation, and 3, the possibility of securing the services of a competent surgeon in this particular branch. The diagnosis of chronic Bright's disease can hardly fail, with care. Edebohls holds that the form of nephritis does not enter into the question of indication or contraindication. Good results, he says, can be obtained from operation in all varieties. He gives his own experience. As regards age, he has performed decapsulation on 9 patients who were 50 years of age or over; 3 of the 9 died within a week of the operation, 3 died after a longer period of time, and one three weeks after the operation, one in ten and a half months after operation, and one five and a half months. Only 2 of the 6 patients were benefited by the operation. Disorders of the heart are also of importance, but he has observed the cardiac symptoms to entirely disappear as a result. There is one cardinal point that should guide us in advising for or against decapsulation for chronic Bright's disease in the presence of cardiac derangements, especially enlargement of the heart and degeneration of the heart muscle. It is the fact as to whether the compensation of whatever lesion may be present is sufficiently good to warrant the assumption that the patient will safely stand the anesthesia. The most ominous single auscultatory sign of predominant dilatation of the heart and danger of sudden death is, in his opinion, insufficiency of the aortic valve shown by an intermittent aortic regurgitant murmur, occurring every third, fourth or fifth beat, or less frequently. If this condition is present and can not be relieved, the patient is very near the end of life, and he advises against operation. The presence of albuminuric retinitis is another contraindication. While he does not say it is absolute in cases of young persons, he would very carefully weigh all the facts before advising it. More experience is required before the last word can be said. The advantages of having a surgeon who thoroughly understands the method are obvious, and the success of the procedure will largely depend on this. He describes his technic, which is not especially changed, excepting that he now advises to always anchor the decapsulated kidney to the dorsal muscles. Another point is the necessity of securing healing by first intention to obtain the best results. Nephritics do not stand suppuration well. He strongly argues for the value of the operation in suitable cases.

12. **Mouth Operations.**—Herzog suggests in order to avoid the aspiration of blood during general anesthesia in mouth operations, the use of an intubator connected with a rubber tubing through which the patient can breathe, the larynx being thus fairly occluded from any accident of aspiration of blood, etc. The patient, he says, will breathe through the rubber tubing, and the anesthesia can be administered in this way as easily as through a tracheotomy tube.

17 A Study of the Tuberculosis Problem in New York City. James A. Miller.
18 A Remarkable Case of Gastric Cancer: Separate Involvement of Cardia and Pylorus: Gain of 35 Pounds in Weight Within Three months of Death. G. W. McCaskey.
19 Postpartum Tubo-ovarian Abscess Causing Hydronephrosis. A. Ernest Gallant.
20 *Ethyl Chlorid as a General Anesthetic. A. F. Erdmann.

14. **Vocal Fremitus.**—Berkeley points out some of the peculiarities of vocal fremitus, especially those which indicate pathologic conditions. The usual excess of fremitus on the right side may be lacking. Ordinarily palpable vibration obtained by putting the four fingers transversely and snugly over the larynx is generally four or five times as great as the right subclavicular fremitus. If this latter becomes for any given case widely variant from this ratio, the condition is pathologic. When the fremitus is equal on both sides, Berkeley considers in ninety-nine cases out of a hundred it is pathologic. The statement made in text-books that vocal fremitus is less than normal in vesicular emphysema is, he thinks, incorrect.

15. **Peritonitis.**—Fowler advocates the elevated head and trunk position in the after-treatment, showing its value by statistics. The salient points in the treatment of these cases are given by him as follows:

(1) A small incision and the avoidance of eventration; (2) thorough cleansing of the primary focus of infection and removal of the appendix. (3) Evacuation and cleansing of all accessory abscess cavities and the pelvis before washing out the peritoneal cavity. (4) A rapid systematic flushing of the peritoneal cavity with peroxid-soda solution followed by hot saline. (5) The continuance of the saline flushing until the sutures are placed, and for the most part tied. (6) The provision of proper drainage for the pelvis either by means of a large glass tube containing a capillary drainage strip emerging through the lower angle of the wound or, in females, by a large caliber rubber tube filled with wicking passed through a posterior colpotomy incision. (7) The drainage of accessory abscess cavities with gauze or wicking. (8) The elevation of the head of the bed to accelerate the drainage of septic fluid into the pelvis where it can be removed through the glass tube or, in case of vaginal drainage, find a ready exit.

20. **Ethyl Chlorid.**—This anesthetic is strongly recommended by Erdmann. It should be chemically pure, given with the proper apparatus and a snugly fitting mask and the dosage carefully regulated. Only two contraindications have been suggested: 1, If the laryngeal aperture is abnormally small, it may be irritated to a stenosis; 2, if kidney disease is present. This latter, however, he does not think a valid objection, as it is not commonly held that the kidney itself suffers harm.

23 Notes on Radium. Francis H. Williams.
24 Vaginal Section in the Treatment of Extra-uterine Pregnancy. Frank A. Higgins.

22. **Sulphites as Food Preservatives.**—Harrington has experimented with the sulphites, sodium sulphite particularly, on cats, and finds that in all the animals except the control one, the kidneys were affected, though the other organs were apparently normal. This substance is largely used as a meat preservative, especially in the popular Hamburg steak, and the necessity of its innocuousness is obvious.

37. **Surgery of Nephritis.**—Sexton considers decapsulation of the kidney a useful and safe treatment, which should be given consideration in every case, but he would not say that the operation is always indicated.

St. Louis Medical Review.

May 28.

38 *Medical Treatment of Appendicitis. Eugene F. Hauck.

38. **Appendicitis.**—Hauck thinks that in many cases appendicitis may be cured by medical treatment, and refers to authorities, especially to a review of the cases occurring in the French army. His own practice is, unless decided symptoms of suppuration are present, to apply ice bags, etc., to the spot. In some very robust persons leeches are applied. Internally he gives ¼ gr. of calomel every hour until the bowels move freely. If needed, a large warm enema of water, repeated if necessary. Opium is given only when the pain is very severe. After all local symptoms have subsided he applies ichthyol externally and occasionally carminatives internally. Only liquid food is given, and none at all for forty-eight hours, with absolute rest in bed for some time, with great care in the diet for several weeks. He has treated a large number of cases, and does not recollect a single instance in which he advised against operation and it became necessary to operate afterward.

39 *Accidental Perforations of the Uterus. D S. Fairchild.
40 Use in Foreign Countries of Immediate Mechanical Dilatation of the Cervix Uteri. L. M. Bossi.

39. **Accidental Perforations of the Uterus.**—Fairchild shows from various records in the literature and his personal observations that the uterine tissue is capable of being perforated with unexpected ease even in the normal condition, and with much greater ease in certain diseased states. While it has been said that the accident is of small importance and without serious results, this allegation must be qualified by the record of 25 per cent. that have proven fatal. Perforations with a sound properly prepared will generally not be followed by serious consequences. Perforations with a curette are much more dangerous on account of the possible laceration of the uterine tissue in the curetted area. When uterine irrigation is added the danger is greatly increased. The treatment will depend on the nature of the instrument used. In case of criminal abortion, the ignorance or dishonesty of the operator will interfere with the discovery of the condition too often and proper treatment can not be instituted. If the perforation is small and made with a clean instrument and irrigation not employed, rest and the application of ice will generally be followed with recovery with nothing more serious than a circumscribed peritonitis. If irrigation has been employed, one of two courses will have to be followed. If the infection is mild, treatment by rest and ice will be sufficient, but if it is of a character to excite a septic peritonitis, vaginal hysterectomy with drainage will have to be employed. In the milder infection there is the danger of chronic inflammatory processes in the pelvic connective tissue or peritoneum leading to abscess formation and the treatment usually demanded for such conditions. If the perforation is extensive the fundus may be delivered through an anterior vaginal incision, and the wound in the uterus closed by suturing, or the choice will be between suturing the wound or a hysterectomy. Hysterectomy is not often demanded as an immediate operation unless there is some degenerative change of the organ, but it is not good surgery to allow an opening of any size to go unrepaired, not only on account of the danger of infection, but on account of possible hernia and strangulation of the intestine.

55 *Experimental Studies on the Etiology of Acute Pneumonitis. Augustus Wadsworth.
56 Hereditary Edema. Arthur W. Fairbanks.

41. **Visceral Crises in Erythema Affections.**—Osler suggests the importance of differentiating these attacks from surgical conditions such as appendicitis, intussusception, etc. He reports cases which point out this necessity. The practical results, he says, to be drawn from the three cases in which laparotomy was performed are: 1. In children with colic the greatest care should be taken to get a full history which may bring out the fact of previous attacks, either of skin lesions, arthritis or intestinal crises. 2. Conduct the most careful inspection of the skin for angioneurotic edema, purpura or erythema.

42. **Changes in the Intercostal Muscles and Diaphragm in Infective Disease.**—Coplin has studied the intercostal muscles in 7 cases; 2 of these were croupous pneumonias with plastic pleurisies, the pneumococcus being isolated from the lung and pleural effusion; 2 were tuberculous lesions of the pleura, and 2 others were cases of acute pneumococcal pleurisies. He found that the muscle fibers showed marked granular change, lack of tingibility or stain reaction; later granular acidophilic deposit around the muscles and interfascicular connective tissue. In the third stage there is a leucocytic infiltration of the muscle similar to that shown by Rohrer. Some fibers appear almost necrosed beside the healthy ones, closely resembling myocardial degenerations of various infectious diseases. There is no difficulty in the identification of organisms that may reasonably be considered pneumococcic. The fourth stage is studied with difficulty unless the patient dies. Small necrotic areas infiltrated by polymorphonuclear leucocytes are really microscopic abscesses. He thinks the tendency would eventually be to a certain degree of muscular sclerosis or a subacute or chronic sclerous myositis. Coplin remarks that the influence of the changes on the thoracic wall are obvious, and a change of respiration must be evident. Such structural alterations in the intercostal muscles possibly clear up the observation that intercostal rheumatism, intercostal neuralgia, etc., are complicating or associated phenomena of pneumonia and pleurisy.

44. **Typhoid and Tuberculosis.**—Anders reports cases of combined typhoid and acute pneumonic phthisis and acute miliary tuberculosis. He points out the importance of the recognition of the condition, the confusion of diagnosis, etc. The Widal reaction may clear up the diagnosis, though often appearing late. A matter of greater clinical importance than to recognize these two disorders when occurring together is the distinction to be made between acute miliary tuberculosis and typhoid and the absence of the Widal reaction, the characteristic eruption and slow pulse of miliary tuberculosis should be especially noted, and a careful search also be made for tuberculosis of the choroid, tubercle bacilli in the blood and

sputum. In doubtful cases attempts should be made to cultivate the typhoid bacillus from any suspicious eruption which may occur. A positive diagnosis, however, is not possible in all cases.

45. **Ulcers in Typhoid.**—Baer has made a careful study of the anatomic position of ulcers in cases at the Cook County and Presbyterian hospitals in Chicago, tabulating and discussing his results. They may involve almost any portion of the digestive tract, excepting the mouth. Involvement of the large intestine was not found in any case in the literature studied, but there were five such cases in the series here reported.

47. **Parotitis Complicating Appendicitis.**—Bunts reports cases; the object of his paper is to emphasize the possibility of the occurrence. The prognosis is generally good. The treatment and prophylaxis are given. The former is the cleansing of the teeth and attention to the buccal cavity. For the latter, hot or cold applications, and where pus is obviously present, evacuation and drainage.

51. **Unilateral Kidney Lesions.**—Krotoszyner and Willard discuss the methods of diagnosing unilateral kidney lesions, and conclude that no one method alone is sufficient. The essential condition, however, is ureteral catheterization, and wherever feasible, catheterization of both ureters. If both urines obtained in this way are subjected to cryoscopy, phloridzin test, urea examination and microscopic examinations, it is possible for us to get a fair idea of the functional value of the kidney and to arrive at safe conclusions as to the intended operative procedures.

53.—See abstract in The Journal, xli, p. 1293.

55. **Etiology of Pneumonia.**—Wadsworth concludes that under normal conditions the bronchi and lung are practically free from the micro-organism; that the secretions of the upper respiratory tract in both health and disease often harbor the bacteria found in pneumonia, pneumococci, streptococci, staphylococci and pneumonia bacillus; that the incitants of pneumonia may be carried to the lung by the lymph channels, inducing an interstitial pleuropneumonitis or by the blood vessels giving rise to metastatic processes, or as is usual by the air passages, inciting the various lesions of pneumonia.

Archives of Pediatrics, New York.

57 *The Reduction in the Tubercular Death-rate in Children in New York City. Hermann M. Biggs.
58 Polycythemia of Congenital Heart Disease. Ira S. Wile.
59 *Tonsillitis a Cause of Acute Nephritis. John Lovett Morse.

57. **The Tubercular Death-Rate.**—The death-rate of children from birth to 15 years of age in the city of New York during the last twenty years from tuberculosis is analyzed by Biggs, who finds a marked reduction of late years. From the beginning with .60 or .70 per 1,000 of the entire population under fifteen years, it has fallen to a little over 0.30 of 1. He thinks with an extension of the regulations which are now being enforced, with wider diffusion of information as to the nature of the disease and larger facilities for the care of advanced cases, there will be a still further and rapid reduction in the deathrate of this disease in the early period of life.

59. **Tonsillitis as a Cause of Nephritis.**—Morse says this supposition is not irrational. Cases seem to prove it. It is probable that this sequence is more frequent than commonly supposed, and that in many cases considered primary the infection enters through the tonsils; therefore, tonsillitis can not be looked on as a disease of slight importance. A disease that can cause acute endocarditis and acute nephritis is certainly one deserving attention. The heart and urine, therefore, should be examined as carefully as in rheumatism or scarlet fever, and the examinations kept up during convalescence.

60 *A Bone Forceps for Use in Tympanic Surgery; Its Value in Safe-guarding the Facial Nerve in the Radical Operations for Chronic Suppurative Otitis Media. Philip D. Kerrison.
61 The Question of Intra-nasal Operation on the Frontal Sinus. Beaman Douglass.
62 Leukemia of the Frontal Sinus in a Case with Supernumerary Sinuses in Each Case. Harold Bailey.
63 *Exanthematous Eruptions Following Throat Operations. Louis Fischer.
64 Cholesteatomatous Disease of the Tonsils. Norval H. Pierce.
65 Calculus in Wharton's Duct Complicated by Suppuration, with Involvement of the Submaxillary and Sublingual Glands. M. D. Lederman.
66 Parosmia: with History of a Peculiar Case. Carl E. Munger.
67 Should Specialists Charge Physicians for Services? S. S. Bishop.
68 The Alter-de Vilbiss Spray Stand. Francis Alter.

60. **Bone Forceps.**—Kerrison describes a form of bone forceps in which the cutting is done from within outward. The blades of the forceps cut horizontally by crossed leverage, sliding on each other. He illustrates three sizes, and claims that they possess the following advantages: Saving of time in removing the roof and posterior wall of the meatus and exposing the antrum. Exclusion of the chisel from the tympanic part of the operation and elimination of the danger which is always present in removing with this instrument the inner margin of the posterior superior canal wall which overhangs the facial ridge. Exclusion of the mallet from the tympanic operation and consequent danger of concussion. Diminished danger to the important structures from the fact that the bone is cut in a direction from within outward, that is, away from the stapes, facial canal and external semicircular canal. Increased safety to important structures from the fact that after the preliminary steps of removing the superior and posterior walls of the meatus, the tympanic landmarks are constantly in sight.

63. **Exanthematous Eruptions Following Throat Operations.**—From his study of the subject, Fischer concludes that the infections of measles, scarlet fever, etc., sometimes following throat operations are present before the operation, and that the latter only hastens the disease by shortening the period of incubation in lowering the resistance of the body. This will account for the cases called surgical scarlet fever, etc., which are true cases of the disorder with infection prior to the surgical procedure.

Wisconsin Medical Journal, Milwaukee.

69 *The Scope of Vaginal Section. J. Clarence Webster.
70 Syphilis as a Cause of Psychoses. Richard Dewey.
71 Neurasthenia. H. H. Albers.

69. **Vaginal Section.**—Webster thinks that it is impossible to make any comparison as regards the safety of the vaginal and abdominal operations, but when operation can be performed equally safely and satisfactorily by either route, the vaginal should be selected. He can not protest too much, however, against making it a routine practice. The size of the vagina must always be an important consideration. The conditions in which he thinks the vaginal route may be selected are occasionally in the removal of small myomata and in malignant disease of the uterus, in uncomplicated retroversion of the uterus, inversion of the uterus, etc. Pelvic adhesions can be satisfactorily dealt with only through an abdominal opening permitting covering of the raw surfaces. Diseased ovaries and ovarian cysts may sometimes be removed, but great care should be exercised. The various methods of incision are described, including the author's, for which he claims the advantage of greater movability of the uterus and more room for intrapelvic manipulation.

72 *Unsettled Questions in Abdominal Surgery. John G. Clark.
73 *The Therapeutic Value of Aseptic Ergot in Anesthesia and Shock. H. Grad.
74 Posterior Introduction of the Forceps. George L. Broadhead.
75 Iodized Catgut. Charles S. White.
76 Floating Liver. D. W. Prentiss.
77 Three Unusual Obstetric Cases. Julius Rosenberg.
78 Intestinal Obstruction Following Laparotomy. W. Sinclair Bowen.
79 A Plea for Early Operative Interference in Cases of Acute Appendicitis, with Report of Cases. J. E. Sadler.
80 *Operative Treatment of Retroversion of the Uterus, with Report of Cases. (Concluded.) Franklin H. Martin.

72. **Abdominal Surgery.**—The questions which Clark thinks should be discussed are whether the normal appendix should be removed in all pelvic operations, and gallstones when discovered. If the right kidney has a range of mobility from 2

to 6 cm., under which circumstances most of them may be easily palpated, what symptoms are pathognomonic enough of a pathologic mobility to indicate nephrorrhaphy? What degree of descent of the stomach and transverse colon requires operative measures for their restoration? Is there a group of symptoms significant of sigmoiditis? In these cases should sigmoidopexy be performed? He would answer these queries as follows:

1. With intelligent patients the question of whether or not the appendix is to be removed should be left to their decision. In the less intelligent class, where the surgeon's judgment must be the guide, I believe the best interests of the patient will be subserved by the removal of the appendix. 2. In every case, unless the patient's condition is a contraindication to any further operation, gallstones, even though they have not produced symptoms, should be removed. 3. Only in instances when the symptoms very directly point to pathologic mobility of the kidney should this organ be suspended as a coincident part of another operation. In my experience the percentage of these cases is not more than one in 150 cases. 4. If the transverse colon is situated at the brim of the pelvis and the lower curvature of the stomach is below the umbilicus, this organ should be replaced and held in position by stitching the gastro-colonic omentum in a transverse line across the upper portion of the abdomen. 5. As to the question of there being a group of symptoms significant of sigmoidtosis, I am as yet in doubt, but I believe that the cases of fixed aching pain at the brim of the pelvis associated with obstinate constipation in the absence of pelvic lesion, are strongly significant of this condition. 6. Although as yet a novel procedure, sigmoidopexy, if only performed in the more exaggerated cases, may offer a hope of correcting this dislocation and relieving symptoms.

73. **Ergot for Shock.**—Grad reports experience with ergot given hypodermically during anesthesia, to combat the nausea and vomiting following, etc. While not wanting to appear too enthusiastic about ergot in nausea and shock, he thinks its use merits attention, and while it may not be prompt in all cases and under all conditions, yet in a very large number of cases it will be of great value in combating the nausea and shock.

80. **Retroversion of the Uterus.**—Martin describes his autoplastic suspension, and gives a summary as follows:

1. A very small percentage of uncomplicated retroversions may be cured by correcting an anterior position of the cervix by lengthening the anterior vaginal wall and shortening antero-posteriorly the mucous membrane of the posterior vaginal vault after the Shucking method. 2. The Alexander operation of shortening the round ligaments is a safe, rational and permanently satisfactory procedure in persistent retroversion in which no pelvic complications exist demanding a peritoneal opening, and should be pursued as a routine operation in such cases. 3. In slight adhesions of the fundus of the uterus with little other pathology to be palpated, a posterior vaginal incision may be made by one accustomed to deep vaginal operation, the adhesions separated and the sacro-uterine ligaments shortened. 4. With slight adhesions present and little pathology to be demonstrated, an anterior vaginal incision is justified in the hands of an experienced operator, provided that he adopts a vaginal round ligament operation for correcting the displacement and never a fixation. 5. When an Alexander operation is contraindicated in a persistent retroversion, because of doubt as to pelvic adhesions or diseased adnexa, it should become a routine procedure to open the peritoneum by a short exploratory incision through the abdominal wall above the symphysis for the purpose of managing the adhesions and diseased adnexa. 6. Some form of simple superficial ventral suspension should be followed as a routine method of retaining the uterus forward in cases where sterility is rendered imperative from the nature of the accompanying procedure, or when the patient has passed the menopause. 7. When the repair of complicating conditions in retrodisplacements requires a laparotomy, but the operative procedure leaves the woman with child-bearing possibilities, a superficial ventral suspension or intra-peritoneal shortening of the round ligaments should be employed to retain the uterus forward. 8. In a small but definite percentage of cases of complicated retroversions where accompanying pathology is such as to cause extensive denudations of the peritoneal covering of the uterus, or where the repair work on the appendages is such as to be liable to lead to dystocia, the surgeon should at once render the patient sterile by amputating the tubes into the horn of the uterus, obliterating them by inversion sutures, and then suspend the uterus. 9. In performing a suspension or an Alexander one important element of danger can be eliminated by substituting for dead permanent suture material my autoplastic methods of securing the suspensory ligaments.

6 Remarks on a Series of 120 Operations for Vesical Calculi. F. A. Southam.

2. **Hematoma and Hematocele.**—Doran reports two cases and discusses the question of the necessity of operation. One was a pelvic hematocele and the other a hematoma; the former was not operated on. In both the general results were good. The second case indicates, he thinks, that hematoma is not so rarely a result of interrupted extrauterine pregnancy as has usually been held. The tubal sac is more likely to discharge its contents through the pelvis into the peritoneal cavity or to burst into that cavity than to rupture between the folds of the broad ligaments. When the broad ligament is opened up in this way instead of hematoma forming, the ovum not rarely continues to develop, constituting the tubo-ligamentary pregnancy. In some cases the ovum is destroyed and true hematoma develops and displaces the pelvic peritoneum upward after the manner of a tubo-ligamentary sac. In such a case the lower part of the hematoma, bulging behind the cervix, may be mistaken for a hematocele occupying the Douglas pouch, though that pouch really no longer exists. Secondly, the hematoma of extrauterine gestation is not as innocuous as compared with hematocele as some authorities teach. The peritoneal capsule may yield, until dangerous intraperitoneal hemorrhage results. Thirdly, there is no question as to the fact that hematocele is a very frequent result of interrupted tubal pregnancy, but he thinks that while the perils of hematoma have been underrated, those of hematocele have been exaggerated, at least as regards the early stages of ectopic gestation. Hematocele often means that the issue of blood from a tubal mole has permanently ceased and it is not certain that the same may not be said in many cases of early rupture of the tube.

4. **Prostatectomy.**—Freyer reports twenty more cases of this operation carrying his work down to the end of 1903. He gives brief notes of the cases. His paper is illustrated.

5. **Suprapubic and Perineal Prostatectomy.**—Deanesly reviews the advantages and disadvantages of the suprapubic and perineal methods. He prefers the latter for the following reasons:

> It is anatomically more direct; it does not inflict a double wound in the bladder, and does not open the prevesical cellular tissue. Again, the whole operation can be performed deliberately and under the direct guidance of sight as well as touch; it permits, therefore, the operator to remove as much or as little of the prostatic overgrowth as the circumstances of the case or the nature of the enlargement render desirable or feasible. Lastly, the drainage of the bladder and subsequent wound treatment are much facilitated by the dependent opening. . . . The preliminary stages of the operation offer a method of exploring the bladder which for many purposes is much superior to suprapubic cystotomy.

8. **Blood and Blood-Forming Glands in Early Life.**—Hutchison's second lecture discusses the rôle of the thymus in blood production and the effects of the lymphatic glands. He finds that there is no absolute rule as to the development of the thymus or its involution. Excessive development is sometimes met with, and is associated with sudden death which has been considered due to asphyxia, but another view, however, is that it is merely an index of a general lymphatic dyscrasia, which entails a general feebleness of resistance rendering the subject liable to sudden death from any cause. The vagueness of the latter theory, he remarks, puts it almost beyond the scope of criticism, but at least in one typical case he could find no increase of adenoid tissue or sign of impairment of health. The blood disorders of infancy differ from those of adults largely in their lack of distinction of type. Clear-cut types are less frequent and occur rarely, at least, in infancy and early childhood. There is one type of anemia peculiar to infancy; that is, the anemia splenica infantum, and it epitomizes in itself all the peculiarities of the anemias of infancy, showing, on the one hand, a marked destruction of red cells with a rapid appearing of the nucleated forms, and showing on the other, by the tendency for the non-granular cells of blood, to be increased, that reaction of the adenoid tissue to unfavorable influences which is so notable in childhood. Secondary anemia is prevalent in early life because of the vulnerability of the blood cells and the poverty of hemoglobin and many influences, especially destructive to blood, are especially likely to act, such as defective diet, etc.

9. **Necroses of the Alimentary Tract.**—The part played by strangulated hernia and anomalies of Meckel's diverticulum are discussed in Corner's second lecture, with illustrated cases.

10. **Nasal Accessory Sinuses.**—Tilley describes his methods of radical operation in suppuration of the antrum, frontal and ethmoid sinuses. He prefers the radical operation—complete removal of the front wall in the frontal sinus. The risk of life depends on the situation of the sinus relative to the neighboring vital structures. In the antrum, aside from the absorption of pus, there is practically no danger. With empyema of the frontal ethmoid and sphenoid sinuses the case is very different. Many fatal cases have been reported. As long as the discharge is free the patient will only suffer from the results of absorption of the septic matter and the annoyances, but a severe cold in the head or increase in the size of polypi or other swellings may produce a retention of septic products and evil

possibilities at once present themselves. The risk of operation depends on the parts involved and the surgeon's familiarity with the region and the technic. The maxillary antrum may be operated on without any appreciable risk, but the reverse holds in case of higher sinuses. Tilley is in entire accord with those that maintain that only complete obliteration or the destruction of the bony cavities offers any chance of radical cure. In case of frontal sinus the anterior bony wall should be removed, and any recesses of the sinus thrown into the main cavity by breaking down of partition walls. The fronto-nasal canal must be enlarged, and suppurating anterior ethmoid cells carefully broken down, or reinfection of the higher sinus will occur. Free spontaneous drainage is essential, and if this is kept up there is no serious danger. Generally speaking, operative manipulation in the ethmoid region will be safe if carried out below the level of the insertion of the middle turbinate. The inside of the sphenoidal sinus should never be curetted, for if a large opening be made in the anterior wall, suppuration will generally cease, if the cavity be frequently cleansed with mild antiseptic lotions. Curettage, especially of the outer and upper walls, may be a very dangerous procedure.

11. **Gastric Ulcer.**—Pasteur has treated all cases of gastric ulcer for the past eighteen months with rectal feeding by plain water enemata at body temperature with good results. It relieves thirst, does away with uncomfortable sensations, the unpleasant taste in the mouth, and the patients are much more comfortable. He says it is a good plan to begin with a five- or six-ounce enema, increasing the volume each time one ounce until ten ounces are easily retained, giving the enemata every four or six hours according to circumstances. In most cases they may be supplemented by small quantities of peptonized milk by the mouth before the end of the week, but in several instances his patients have gone without food for ten days or a fortnight, and in one or two cases for nearly two or three weeks without any complaint or indication that they were the worse for the abstinence. The method, he thinks, gives at least as good results as the ordinary nutrient enemata. It is simpler to carry out, more endurable to the patient, and does away with the unpleasant and offensive daily wash-out.

15. **Hare-Lip.**—Murray has made inquiries as to the geographical distribution of hare-lip. He believes that it occurs among all nations, and that the practice of putting to death deformed children will probably account for its absence in some regions, as Central Africa and Hawaii.

18 *Syphilitic Patches on the Scalp. Umbert (Barcelona).—Les plaques crouteuses du cuir chevelu.
19 *Le dosage en radiothérapie et son tracé graphique. Béclère. Abstract.

17. **General Conception of Cutaneous Affections.**—Brocq recognizes two great groups of dermatoses, the true morbid entities and the cutaneous reactions. The first group includes the artificial, parasitic and microbian affections, and the second group the reactions on the part of the skin with or without nervous or nutritional elements or deviation of the tissues from the normal type. He shows in graphic form how the true morbid entities described in the text-books may blend into others or be complicated by others or by mere cutaneous reactions, so that each, instead of being a clearly defined syndrome, may be nebulous around the edges and the transitional forms may mask the true entity in many cases.

18. **Syphilitic Patches on Scalp.**—Umbert regards any dry, circumscribed lesion with infiltration, located on the scalp, as suspicious of syphilis. The eruptive element is drier in case of syphilis than of other scalp lesions. Several hairs are always involved instead of a single hair, as in acne. Another differentiating point is that acne usually attacks the face as well as the scalp. The sudden onset of the syphilitic patch is also a differential feature. There is no inflammatory environment and no pain. The patch usually persists unmodified by general treatment until it is supplemented by local coal-tar or sulphur applications, when it rapidly subsides.

19. **Dosage in Radiotherapy.**—Béclère urges the general adoption of a chart as a means of keeping the record of cases submitted to radiotherapy. The therapeutic reaction to the *x*-rays depends on the amount of rays absorbed. He uses the Holzknecht chromoradiometer (illustrated in THE JOURNAL, xxxix, page 1075), and proclaims that it is no more necessary to induce a dermatitis in *x*-ray treatment than to induce stomatitis in mercurial treatment of syphilis. The aim should be to have the maximum quantity of rays absorbed at each exposure compatible with the integrity of the integument, skin or mucosa. Also to have the interval between the exposures as short as is compatible with the integrity of the integument, skin or mucosa. The maximum dose is less for the young than for adults, and less for adults than for the aged. When the skin is normal this dose varies for the face from 3 to 4 Holzknecht units; for the joints, 4 to 6 H. units; for the trunk, scalp, palm and sole, 5 to 7 H. units. When the skin has been the seat of a recent inflammation and especially if the inflammation still persists, these figures should be reduced by 1 or 2 H. units. On the other hand, these doses can be far surpassed in case of an ulcerating surface. Seven days is the usual interval he prefers. The chart he recommends is an ordinary fever chart, the dates marked off above as usual and the horizontal lines indicating the number of H. units at each sitting. The curve is thus represented by a vertical line representing the number of H. units, followed by a horizontal line representing the number of days that elapse before the second exposure, when the line runs straight up as before through the proper number of H. units, then horizontal again through the days of the interval before the next exposure. The curve forms thus a series of steps, like a flight of stairs, on which can be read at a glance the dosage, intervals and number of exposures. He gives an illustration of a typical chart and describes several cases to show the benefits derived from such accurate dosage. He quotes Sabouraud's experience that 4.5 to 5 H. units are the proper dose for the treatment of alopecia areata. This causes the necessary falling out of the hair without any apparent inflammatory reaction. (See page 1459.)

Bulletin de l'Académie de Médecine, Paris.

24 *Anémie ankylostomiasique des mineurs. A. Manouvriez (Valenciennes).
25 *Myopathie scapulo-humérale. Procédé chirurgical pour remédier à l'impotence des membres supérieurs. Raymond.

20. **Trypanosome Diseases—Mbori and Soumaya.**—Cazalbou inoculated sheep, rats, mice and dogs with trypanosomes derived from dromedaries in the French Soudan affected with "mbori" or the fly disease. The tsetse fly is not known in that locality, but another fly, the *Tabanus soudanensis*, seems to be the source of infection. Laveran discusses whether the symptoms of the disease and the properties of the trypanosome differ from those of other similar affections with which we are acquainted. There are certain features which indicate that it is a distinct morbid entity, but this can be decided only by testing to see whether animals immune to surra and nagana are susceptible to mbori and vice versa. The trypanosomiasis observed in camels by Brumpt at Ogaden and by Sergent in Algeria evidently closely resembles that noted by Cazalbou at Timbuctoo. The soumaya affects zebus and cattle and the trypanosome causing it closely resembles that of mbori. The natives say that it is impossible to keep any domestic animals on the banks of the Bani river. To test this Cazalbou sent four horses down to the river and all developed symptoms of trypanosomiasis after a two to four days' stay. The symptoms in some seemed to be those of nagana. The prevalence to such an extent of trypanosome diseases in the French Soudan was never suspected before.

21. **Paraffin Prothesis.**—The various syringes devised for this purpose have aimed to keep the paraffin warm and thus soft enough for injection. Lagarde accomplishes this result by forcing the paraffin out by means of a screwing piston, the mechanical force of the screw forcing a fine stream of cold paraffin out at the tip. This fine stream is easily worked into place and molded into the proper shape. In the discussion of the subject Hallopeau reported an unfortunate experience with paraffin prothesis. A syphilitic defect of the upper part of the nose was treated by injection of paraffin, which did not accomplish the desired result, but rather aggravated the deformity, as it formed two bunches each side of the nose. A second attempt was made later and it was followed by the instantaneous loss of the sight of one eye. The blindness could not have been due to a manifestation of the syphilis, as the patient had been free from symptoms for years, and syphilitic blindness never comes on with such suddenness. He has also observed that paraffin prothesis in the breast is liable to soften and subside in time, as also when it is used in place of the testicles.

24. **Miners' Anemia.**—When mines are well ventilated they become cooler and thus the conditions are rendered unfavorable for the growth of ankylostomata. The miners say that wooden props in the mines are "unhealthy," and experience has shown that they are right in one sense, as the wood becomes a nest for these parasites, especially when the bark is left on. Manouvriez reviews the history of ankylostomiasis in France, and states that Calmette's investigations are now revealing that it still exists there.

25. **Scapulo-Humeral Myopathy.**—Raymond's patient was a young man presenting a severe typical case of Erb's progressive atrophy of the muscles. He was treated by suturing the right scapula to the fifth and sixth ribs, a silver wire passed through holes in the scapula and then around the ribs, after excision of interposing muscles. Some of the muscles were transplanted and a plaster cast was applied for forty days. He can now, three months later, raise his hand to his head and otherwise use his arm naturally. He is now clamoring to have the other side operated on in the same way.

35 *Prevention of Infectious Diseases in the School. F. Hueppe.—Verhütung der Infectionskrankheiten in der Schule. (Commenced in No. 18.)
36 *Zur Radiotherapie. O. Lassar.

26. **Formaldehyd Disinfection.**—Bonhoff reviews the various disinfecting apparatus on the market and asserts that Flügge's formula of 2.5 gm. formaldehyd to the cubic centimeter is too small a dose to be effectual. For ordinary cases 5 gm. formaldehyd per cubic centimeter and seven hours of exposure are necessary. When the conditions are unfavorable the proportion of formaldehyd should be twice this.

32. **Transmission of Tuberculosis.**—Heller refers to the experiences at Kiel including Wagener's finding of 76 cadavers with primary tuberculosis of the intestines and mesenteric glands in the course of 600 necropsies. Also Hof's finding of primary tuberculosis of the digestive tract without involvement of the lungs in 16.6 per cent. of 15,000 necropsies, and 8.5 per cent. additional in which these lesions in the digestive tract coincided with lesions in the lungs, the total thus being 25.1 per cent. of the entire material. In the country around Kiel the milk is very seldom boiled or pasteurized, while in Berlin the opposite rule prevails. He thinks that this explains the larger proportion of tuberculous infections of the digestive tract in the former. The evidence to date is overwhelmingly in favor of prophylactic measures against tuberculosis infection by the mouth. Infection from inhalation may be primary, in the alveoles, bronchi or lymph follicles, or secondary by inhalation, or through the blood or lymph. He gives examples of each of these six varieties.

34. **Cancer in Hernial Sac.**—Out of 104 cases in which laparotomy was performed for myomectomy, with supravaginal amputation, Sperling had occasion to note in 2 cases the development of a cancer in the ventral hernia which occurred later at the site of the incision. The interval was four and seven years. The cancer was in the thin-walled hernial sac and was inoperable when discovered. In both cases a truss had been worn for several years. The mechanical irritation from the truss may have been aggravated by the buried suture left in the peritoneum.

35. **Prophylaxis of Infectious Diseases in Schools.**—Hueppe's address as delivered at the School Hygiene Congress was summarized on page 1243. Further points are his remark that children's diseases run a milder course the older and consequently the more resistant the children. He also referred to the greater resistance of children who play out of doors all the time even with some member of the family sick in doors. As soon as these children are kept in the house or sent to school they are liable to develop the disease. This accords with the experience in military circles that the best means of stamping out an acute epidemic disease is by thorough ventilation, possibly taking out all the windows. It emphasizes the importance of ventilation in schools. In case of a school epidemic at the beginning of the school year, when the lessons are of paramount importance, prophylaxis should be restricted to isolating the sick only, while the well children should not be debarred from school. Toward the end of the school year, however, the measure of closing the room or school is not so formidable, and on account of the remarkably favorable influence of playing out of doors, the children may be dismissed and given this opportunity as a means of arresting the epidemic. Whooping cough may be transmitted by indirect contact or dried material for a time, while measles seems to require the fresh, moist virus and direct contact for its transmission. In case of measles, the Koplik spots may reveal the existence of the infection in suspects before the contagious stage is reached. Chicken-pox, mumps and rötheln allow the diagnosis of the disease and isolation of the patient in time to prevent infection of others, although he knows of one instance in which an epidemic of mumps could not be arrested until the school room was closed. Contagion "through the air" in scarlet fever and measles probably occurs by germs in the droplets of sputa. He thinks that both are most infectious in the earlier stages, although in case of scarlet fever not until there are definite manifestations in the throat. He does not place much faith in the transmission of scarlet fever in the later, desquamating stage or by dried material, and regards this as highly improbable in case of measles. Indirect transmission of scarlet fever, as in milk, is liable to occur. Diphtheria germs are not very long lived and indirect transmission of the disease is of extremely rare occurrence. But the fact that it does occur occasionally should impose the rule that all material used in teaching children to sew, patchwork, etc., should always be effectually sterilized by steam or dry heat before being given out again. After the age of 5 children are much more resistant to the inroads of diphtheria, although the germ is practically ubiquitous. The predisposition is an important factor, also the fact that the disease declined during the last century nearly to its final extinction, then about the middle of the century it became prevalent again, and since the beginning of the nineties has been declining again. He agrees with Gottstein that 90 to 98 per cent. of all children born now display such a degree of immunity that they can pass through two or three repeated infections with the diphtheria germ without danger. The children of gypsies are entirely immune. In regard to disinfecting school rooms he thinks the delay of the inevitable "red tape" renders its results illusory; and he advocates instead thorough daily cleaning of the room and ample ventilation as

the best mode of combating infection. He adds: "Must we wait for some disastrous epidemic to teach us the lesson to clean the rooms every day?" Oiling the floors facilitates wet cleaning. He thinks the brush and hose attachment invented by Professor von Fritsch of Vienna a valuable means of thorough cleaning with constant washing through the brush. Where wet cleaning is not practicable the vacuum cleaning apparatus should be used. Some such cleaning measures should be applied daily. Eye affections are more serious the younger the child, and fully 14 per cent. of the cases of blindness in children are due to infectious children's diseases. The habit of swallowing sputa is swinish, and is especially dangerous for children, as they are peculiarly susceptible to infection by way of the digestive apparatus. Not back to nature, but forward to health should be our motto, and preventive hygiene should be supplemented by constructive or positive hygiene.

36. **Radium Treatment of Cancer.**—Lassar remarks that notwithstanding radium is so expensive yet the cost of applying radium treatment on the whole is much less than that of an *x*-ray apparatus and its maintenance. He uses the radium in a flexible lead tube on a mica plate which allows it to be placed exactly over the desired spot. At the first indication of irritation, swelling, redness or pigmentation the exposure is suspended and time enough allowed for the irritation to entirely subside. The one essential in radium treatment is medical oversight. Fine results have been attained in treatment of psoriasis, inflammatory edema and inflammations of all kinds in the face, neck and hand. An especially favorable field for radium treatment is that afforded by the inoperable recurrences of mammary cancers. They are superficial, as the gland has been extirpated, and the recurring nodules can be influenced by the radium and practically cured. A number of typical cases of cancers cured by the radium are illustrated. All had been declared inoperable beforehand, or the subjects had refused an operation, and now there is not the slightest indication for surgical intervention. The radium is in constant use at his clinic from morning to night and not a single mishap has occurred in the thousands of applications.

37. **Inoculation of Ape with Syphilis.**—Lassar's illustrations testify to the success of his inoculation of an ape with syphilis. He remarks that the results will serve as a control for persons who claim to have discovered the bacillus of syphilis. All they have to do is to inoculate a chimpanzee with the alleged causal germ. A negative result proves nothing, but a positive one would be strong testimony in favor of their assertions.

38. **Roentgen Treatment of Cutaneous Affections.**—Schmidt thinks that the action of the *x*-rays on the tissues which induces the hair to drop out, at the same time renders the cells an unfavorable culture medium for bacteria and they die, although not killed directly by the rays. On the whole, this mode of treatment accomplishes more in many cases than all our other therapeutic measures. He prefers a tube which shows up the bones of the hand a dark gray. In treatment of cancer he has had fine results when the growth was superficial, but has never witnessed any special effect on subcutaneous growths. One of his most satisfactory cases was a dry, chronic eczema with intolerable pruritus. It healed under the *x*-rays, but the pruritus recurred again after six weeks, but subsided again under renewed application of the *x*-rays.

41. **Progress in Phototherapy.**—Under this heading Strebel describes his technic and the special appliances he has devised for the purpose. One is his "electro-photo-cautery" by which the rays of a volta arc light from a current of 2 amperes are focused on the skin strong enough to burn it. The moment the rays are focused on the spot there is total ischemia, the same as in application of superheated air. Living tissue offers greater resistance on account of the blood circulating through it, while morbid or dead tissue rapidly chars under the influence of the rays. Moles, warts, varices, angiomata, etc., are rapidly destroyed by this action; chancroids heal in three weeks, open boils, tertiary syphilitic ulcers, sycosis and other superficial affections are rapidly cured, as also acne. He reports two cases of lupus erythematodes cured in a single application. The "photo burn," as he calls it, has also definitely cured a number of cases of lupus. This electro-photo-cautery does not supersede but is a valuable adjuvant to Finsen treatment, and may be associated with the latter, thus shortening the course of treatment. He has further devised an apparatus for applying phototherapy to inaccessible cavities. He focuses the light of the sun or of a powerful volta arc light on the rounded top of a short quartz cylinder which collects the rays and focuses them on the rounded top of a second similar cylinder below. By this means it is possible to transmit the light through a system of quartz cylinders as far into the interior of cavities as may be desired. In conclusion he gives an illustration of his lamp for phototherapy for which he claims a number of advantages over Finsen's and other similar lamps. He regards the pigmentation observed after the inflammatory reaction to the light as due to quite other causes than the latter. The light induces a primary irritation of the nerves in the exposed region, entailing inflammation as a trophic reaction differing essentially from the pigment reaction. He exposed an albino patch on a partial albino to the action of the focused light. A typical inflammatory reaction followed, but there was no pigmentation. After one exposure to the light the nerves of the part become accustomed to the irritation, and the inflammatory reaction grows less and less or does not appear at all. He thinks that this nervous influence is best shown by the rapid healing of alveolar pyorrhea under phototherapy after resisting all other known measures. This lesion is probably due to trophic malfunction with secondary bacterial invasion. The phototherapy stimulates the nerves to normal function and as they regain tone the tendency to suppuration subsides. The action in lupus is probably identical. The influence of the light stimulates the trophic nerves to such activity that the processes of regeneration in the diseased tissue soon result in rendering them unsuitable for culture media for bacteria, the latter die off and the lesion heals. Anything that has an influence on the albumin metabolism is liable to alter the conditions in such a way as to render them toxic for bacteria. This is the explanation of the success of serum treatment and inoculation. The introduction into the organism of some strange albuminoid substance modifies the albumin metabolism. The same explanation may apply to the effects of phototherapy. The light may modify the albumin metabolism in the tissues exposed and thus stimulate them to normal vital processes.

43. **Treatment of Eczema.**—Lassar thinks that careful investigation will generally reveal the primal cause of the ecze-

ma, the use of some cosmetic or substance needed in the daily occupation, such as turpentine by artists, contact with certain plants, etc. When this is discovered the affection will soon heal if kept from further irritation. Great progress will be realized when persons with cutaneous affections will return to the physician for a systematic, passive course of treatment, the measures applied varying with the conditions found at each visit. The principal trouble in skin diseases is the damage wrought by self-medication. The main point in treatment is to ward off sources of further irritation. The use of powder, salve and dressing is chiefly to prevent the scratching of the itching region. X-ray treatment is proving more and more effective and reliable for many cases of eczema, particularly on face and hands. After the preliminary procedures the *x*-rays are able to cure many cases without the tedious salves and pastes.

44. **Specific Vaginal Treatment of Syphilis During Pregnancy.**—Vörner tabulates the results of treatment of 40 pregnant syphilitic women by mercurialized vaginal suppositories. He makes the suppositories out of equal parts of lard and mutton tallow, with 12 to 15 per cent. mercury, a total of 3 to 5 gm. It is introduced and pressed against the mouth of the uterus by a tampon. The tampon must be non-absorbent, and is, therefore, impregnated with tannin and glycerin or alum and glycerin. The tabulated results show a favorable influence of this simple specific treatment on the course of the pregnancy and the morbidity of mothers and children, when the latter receive suitable care after birth and breast milk, with specific treatment of symptoms. Neglected, poorly nourished children succumbed in about the same proportion as among similar children of untreated mothers. He thinks this classification of children with inherited syphilis would be a good basis for comparative statistics. Where the conditions are favorable, the vaginal method may be applied with good prospects of success, but where they are not, the most that can be hoped is to bring the woman to normal termination of her pregnancy.

46. **Dietetic Treatment of Skin Diseases.**—Lassar reiterates that dietetic measures are of the greatest importance for the cure of various cutaneous affections. Psoriasis, for instance, is unmistakably benefited by refraining from meat. Cheese is liable to aggravate certain skin diseases or possibly induce them. All kinds of erythemata and rashes with exudation are benefited by calomel purges, followed by a course of mineral waters. Salicylic medication is a valuable adjuvant. The salicylic acid seems to attack the morbid process like an antitoxin, and paralyze the evil effects of the poisons circulating in the blood. The subject must learn what articles of food he must avoid, and should strive to eat at regular intervals and in small amounts. A single hastily eaten meal when he is overfatigued, overheated or irritated may affect him like ingesta containing ptomains. In case of prurigo the nervous system must be soothed and sleep restored. Eczema frequently develops after the prurigo, and both may be avoided by keeping the bowels in good order, avoiding excess of bread and potatoes, and all other causes tending to induce flatulence. Prurigo patients are usually constipated, with hard stools. The tendency to furuncles and phlegmons in diabetic and gouty subjects may be combated by putting the patients on a sugar-starvation diet. So soon as all substances are avoided that form or become transformed into sugar, the tendency to furuncles subsides. The excess of sugar in the tissues affords fine culture media for the pyogenic germs. When this excess is avoided the germs cease to colonize in them, irrespective of whether the elimination of sugar is physiologic or pathologic. The same reasoning and conclusions apply also to uric acid in gout. Any intoxication may affect the skin and reduce its resisting power. He defines scrofula as a lesser resisting power due to inherited weakness and insufficient nourishment or care, and insists that everything which tends to enhance the resisting powers aids in curing the local affection. Obese subjects should diet to reduce their weight, and by this means avoid cutaneous lesions from friction between folds of the skin, etc.

60 Ein verbessertes Tonsillotom. F. Rosenfeld (Berlin).
61 Hämaturie als einziges Symptom Barlow'scher Krankheit. E. Neter (Berlin).

54. **Etiology and Pathology of Affections Due to Distomum Felineum.**—Askanazy has been able to establish that the cat leech or *Distomum felineum* causes a characteristic syndrome in man and, further, that it requires an intermediate host to complete its life cycle. He has also discovered this intermediate host. It is a small, common river fish, the *Leuciscus rutilus*, and one of his 4 patients confessed to eating these and other fish raw. In the 3 cases in which necropsy was possible a colloid carcinoma was found in the liver in each, and these parasites were numerous in it and through the biliary passages. This distomum is common in many localities, but he does not know of any previous publications in regard to lesions induced by its presence.

55. **New Antidysentery Serum.**—Rosenthal's serum is derived by inoculation of animals with first dead cultures, then living cultures, and then the toxins. The technic is to be described in detail in the *Centralblatt f. Bakteriologie* by Gabritschewsky, the chief of the Bacteriologic Institute. Out of 157 dysentery patients treated with this serum, only 7 died with indications of uncomplicated dysentery, and one was 75 years old. Three of these fatal cases were not seen until the end of the first or second week of the disease. The percentage of mortality was reduced by one-half as compared with the course of the dysentery in other patients not receiving the serum, and also in previous years and in other hospitals. When it could be given in the course of the first three days recovery was prompt in one or two days. Marked benefit was apparent from its use, even in the advanced cases with small pulse, cold hands and feet, the sphincter already paralyzed and bloody slime dripping from the anus. The stay in the hospital was very much shorter than that of dysentery patients elsewhere and of the controls.

56. **Alimentary Levulosuria in Liver Affections.**—Chajes reports personal experiences, and states that the number of patients known to have liver affections and tested for alimentary levulosuria is now 84. Of this number, 86.9 per cent. responded positively to the test, while only 15 per cent. of 99 persons free from any liver affection gave a positive reaction. He adds that 11 cases of syphilitic icterus tested by Samberger, all without exception responded positively. (Strauss' article calling attention to this mode of differential diagnosis of liver affections was summarized in these columns at the time.)

57. **Forms of Cutaneous Tuberculosis Resembling Acne.**—Bettmann regards the lesions he observed on 2 patients as a complication or a retrogressive stage of the ordinary forms of cutaneous tuberculosis. The process is by no means an ordinary inflammation as in common acne, but is a tuberculous growth with secondary suppuration. The suppuration always occurs in the center of the papule, and after evacuation of the pus the form of the papule shows the nature of the primary growth. The marginal infiltration in lupus follicularis is always evident under pressure from glass. He found tubercle bacilli in some of the pustules and, encouraged by this fact, he sought to obtain bacilli from lupus pustules by inducing suppuration by injection of various fluids. He was successful in only one instance, finding 2 bacilli in a single lupus focus after slight suppuration induced by injection of a very weak solution of potassium catharidinate.

Addresses.

BENJAMIN RUSH.

AN ADDRESS DELIVERED AT THE UNVEILING OF A MONUMENT ERECTED BY THE AMERICAN MEDICAL ASSOCIATION TO THE MEMORY OF BENJAMIN RUSH IN WASHINGTON, D. C., JUNE 11, 1904.

J. C. WILSON, A.M., M.D.
PHILADELPHIA.

Mr. President, Members of the American Medical Association, and Honored Guests:

It is proper for me to express my appreciation of the high honor which you, through your officers, have conferred on me in delegating to me the duty of addressing you on this occasion. The sentiment of elation which I might otherwise feel is tempered by a lively sense of my unworthiness for the task. It is, however, a satisfaction to find myself associated in the work of thus commemorating the life and labors of the most distinguished of American physicians with Mr. Perry, the sculptor, to whose talent we owe the beautiful and lifelike statue, and with Mr. Metcalfe, the designer of the pedestal on which it rests.

More than twenty years have elapsed since the Rush Monument Committee was appointed. Of its original members, Gihon, Henry M. Smith, Kinloch, Gordon, Rohé, Murphy, Toner, and Henry, all but one have gone over to the majority. S. C. Gordon of Maine alone remains.

At no time in its long existence has the committee lacked energy or insistance; but at the close of its labors the monument is on a scale far less commanding than that which those who conceived the plan first had in mind. To those on whom at the last rested the decision between longer waiting and present casting of the molten metal, the fact that our statue is no colossus does not seem a fault.

Nearly a century has passed since Benjamin Rush was gathered to his fathers. To his contemporaries he was a man not unlike other men, having his virtues and his faults, a good citizen, a skillful physician, kindly, courteous, benevolent, and having on occasion much fight in him. He was even known to have some fame in distant lands, chiefly because of a wonderful, clear narrative of the bilious yellow fever of 1793 which he had written. To us, who see him through the vista of one hundred years, he stands, not, indeed, the most conspicuous figure of a time brilliant with heroic men and deeds, but great among the greatest, and certainly the most striking and impressive figure of the medical life of America at that period or any period since.

The story of his life is a familiar one.

Benjamin Rush was born Dec. 24, 1745, old style, and died April 19, 1813. He came of yeoman stock. For four generations his paternal ancestors, descendants of John Rush, who had been captain of a troop of horse under Oliver Cromwell, and had followed William Penn to Pennsylvania in 1683, had been colonists. The family settled in Byberry Township, thirteen miles northeast of Philadelphia, and lived and died as farmers. It is said that his father and grandfather were also gunsmiths. It was here that Benjamin Rush was born.

Little is known of his boyhood. He left Byberry on the death of his father and came, at the age of six, with his mother and her other children to Philadelphia. Three years later he was taken by his uncle, the Rev. Dr. Samuel Finley, afterward President of Princeton College, as a pupil in the academy over which he presided at Nottingham, Southern Maryland. Here he spent five years, studying hard. acquiring a good knowledge of the Greek and Latin classics and a fine facility in the use of his mother tongue. At the age of fourteen he was sent to college at Princeton, from which institution he was graduated a Bachelor of Arts at the following commencement, 1760, being still in his fifteenth year.

Under the influence of Dr. Finley he was put to study medicine with Dr. Redman, in Philadelphia. Here he remained six years. During this period he had unusual opportunities for the study of his chosen profession. As a pupil he was most diligent and studious. Among other things, he translated the Aphorisms of Hippocrates into English, and made extensive notes of a circumscribed epidemic of yellow fever, which prevailed in the lower part of Philadelphia, along the shore of the Delaware, in 1762.

It was at this time that he began the habit of keeping a diary, which he continued through life. Some of these volumes, unfortunately much mutilated, are now in the possession of the Philadelphia Library.

At the age of twenty-one Rush went to Europe and spent two years in Edinburgh under Cullen, with whom he became a great favorite. He was graduated at the Medical School in 1768, and defended the thesis, "De Concoctione Ciborum in Ventriculo."

Shortly after obtaining his degree he went to London, where he spent several months in attending lectures, visiting the hospitals, and in other work of a professional nature. Benjamin Franklin, then in London, took a warm interest in the welfare of the young physician. Through him he made the acquaintance of many prominent persons, especially in his own profession, and it was through his influence and by means which he furnished that Rush went to Paris for a short time.

While abroad he had given much attention to chemistry, and on his return he was at once elected to the chair of chemistry of the College of Philadelphia, at that time fortunately vacant. His success as a teacher was quickly established. At the same time he sought with equal success to make himself known as a practitioner.

Even at this early period of his career he manifested great interest in political affairs. His leisure hours were devoted to the cause of the abolition of slavery in the colonies, to the advocacy of temperance, and to the promulgation of a knowledge of public and personal hygiene. He gave popular lectures on these subjects and wrote much for the newspapers. He became an active member of the American Philosophical Society, having been elected in 1768, and filled successively the offices of curator, secretary, curator, and vice-president without interruption from 1770 to 1801. On several occasions he delivered formal addresses before that body. The first of these papers, and one of the earliest and most important of Rush's publications, was "An Inquiry into the Natural History of Medicine Among the Indians of North America, with a Comparative View of Their Diseases and Remedies with Those of Civilized Nations." This address, delivered in 1774, when Rush was but twenty-nine years old, was a masterpiece of close observation, mature thought, and clear reasoning. It contains a most important collection of facts relating to the red men of that period, and many sage observations concerning the effects of exercise, fresh air, and cold water on the health, and as curative agents.

Rush took an active part in the politics of the stirring period which led up to the Revolution. He was a member of the Provincial Conference of Pennsylvania, and, with James Smith, served on a committee to consider and report on the question as to the expediency of the declaration of independence by Congress. The report of this committee, which is generally attributed to the pen of Rush, contained much that was incorporated into the Declaration, and urged that measure with great force. He subsequently became a member of the Continental Congress, in which he served nearly seven months, becoming one of the signers of the Declaration of Independence, which had been adopted prior to his election.

In January, 1776, he married Julia, daughter of the Hon. Richard Stockton of New Jersey. Of this union there were many children. He was then thirty-one years old. The same year he was appointed Surgeon-General of the Middle Department, under Shippen. The following year his title was changed to that of Physician-General. Two years later he resigned from the service.

From this period his life was that of the practitioner, teacher, and writer—a life of marvelous activity and influence. He was elected a member of the medical staff of the Pennsylvania Hospital in 1783, and continued in the service of that institution until his death, a period of thirty years. He was one of the founders of the College of Physicians of Philadelphia, and his name appears in the list of the Senior Fellows published with the constitution of the College in the *Pennsylvania Packet and Daily Advertiser*, Feb. 1, 1787. Having been an active fellow of the college from its foundation, he tendered his resignation in a brief note, accompanied with the gift of a copy of Wallis' edition of the works of Sydenham, on Nov. 5, 1793. His resignation was accepted and the secretary directed to thank him for the gift of books.

During the period that Philadelphia was occupied by the British medical teaching was abandoned, but about the time of Rush's return it was resumed, and the Medical School was reopened in 1778. In 1781 Rush was lecturing on chemistry in the new University School. Two years later he became professor of chemistry in the old college, a position which he held until, on the death of Morgan, in 1789, he succeeded to the chair of the theory and practice of medicine. At length, in 1791, when the two schools were united in the Medical Department of the University of Pennsylvania, he was elected to the chair of the institutes of medicine and clinical medicine. When Kuhn resigned the chair of practice, in 1797, Rush undertook the duties of that position in addition to his previous work, and was formally elected to the professorship in 1805. He continued to deliver the lectures on the institutes and practice and to hold the medical clinics until his death.

With all his absorbing and time-consuming professional work, Rush maintained his interest in public affairs. He was resident Port Physician, 1790-1795; a member of the Convention of Pennsylvania for the Adoption of the Federal Constitution in 1787, and was appointed by the President, John Adams, Treasurer of the United States Mint in 1799, an office which he held until his death, fourteen years later, and in which he was succeeded by his son. He died April 19, 1813, after an illness of four days—probably pneumonia. According to a correspondent of Lettsom, the fatal disease was typhus fever.

The end found him, at the age of sixty-eight, devoted as always to the welfare of his fellows, healing the sick, teaching, absorbed in public affairs, busy with his pen. In the warfare against vice, ignorance, and disease he died as he had lived—on the firing line. Hosack tells us that his last deed was an act of charity, and his last words the injunction to his son to "Be indulgent to the poor."

> Nothing is here for tears, nothing to wail
> Or knock the breast; no weakness, no contempt,
> Dispraise or blame; nothing but well and fair,
> And what may quiet us.

His death created a profound impression not only in Philadelphia, but throughout the United States. His numerous writings had made him known on both sides of the Atlantic. In his own country his students and private pupils numbered thousands, and had carried with them to every state in the Union a sense of personal regard and friendship such as is given to few teachers to arouse. He was a really great practitioner, and those who had been his patients were scattered throughout the land. He was one of the few surviving signers of the Declaration of Independence, the close personal friend of many public men, among them Jefferson and Adams, and had himself served his state and country in many offices, and served them well. He was essentially a man of the people, and was as widely loved as he was widely known. His death, coming quickly as it did, caused deep and widespread grief, and he was universally and sincerely mourned.

In person Dr. Rush was above the medium height and slender. His features were strongly marked; his nose aquiline; his eyes bright and piercing; his mouth sensitive and full of expression; his countenance at once animated and dignified, as shown by the portrait by Sully in the Pennsylvania Hospital. His manners were courteous and affable, and there was in his demeanor a charm that won to an unusual degree the admiration and regard of those with whom he came in contact. His voice was most agreeable; he excelled in conversation and was a gifted and pursuasive orator. As a teacher he was singularly sympathetic and impressive. His success in these particulars was, however, not so much due to his personal gifts as to a lively imagination, a well-stored and highly cultivated mind, and a most retentive memory. His industry was prodigious. Work was his recreation. In all things he economized time by the most systematic use of it. His energy and capacity for work were the more remarkable in view of his rather delicate health in early manhood. At the conclusion of his essay on the Treatment of Pulmonary Consumption, he states that he had derived from his paternal ancestors a predisposition to that disease, and that between the eighteenth and forty-third years of his life he had occasionally been troubled with many of its symptoms. After this period his health improved, and toward the close of his life he frequently alluded to his excellent health, which he attributed to systematic work, regular habits of living, and temperance.

Rush was in the highest sense a man of affairs and a scholar. No subject of general interest escaped his notice or failed to arouse his attention. He was an omnivorous reader and made voluminous notes, not only of passing events, but also of the suggestions and comments on them which arose in his mind. As a thinker he was far in advance of his time, advocating civil and religious liberty, temperance, the abolition of slavery, the establishment of free schools, the higher education of women, the proper care of the insane, and international arbitration as a means to universal peace. Lettsom held that "a long and willing abode amidst stupendous mountains, boundless forests, expansive lakes, a pregnant and extensive soil, and a climate suitable to a rich cultivation is incompatible with servility of mind and dependence of condition," and attributed to these physical causes the political agitation of the colonists and the energy, fecundity and luminous action of spirits such as that of Rush. Nor were the teeming thoughts lost on the air; not only were they penned in his note-books, but also on the printed page. He was a constant writer, and throughout his pages the scientific spirit, wise judgment, lofty patriotism, devotion to mankind and deep religious feeling are everywhere apparent.

Yet he had his bitter foes. There were many who ardently hated him in life; there are those who magnify his faults now that he has been so long dead.

One medical historian* tells us that "in spite of his general benevolence he was dogmatic, impatient of contradiction, and often unreasonably resentful."

Does this writer forget David and the imprecatory Psalms?—

> Consume them in wrath, consume them.

Or:

> Let their habitation be desolate, and let none dwell in their tents.

Even the righteous can call down vengeance on their enemies.

But Rush does not appear to have sought quarrels or to have invoked the vengeance of heaven on his foes. Tenacious of his own opinions, he was not very tolerant of those who opposed him. He thought that much harm was done by the French physicians and his colleagues who treated the yellow fever with bark, wine and cold baths, and attributed at least two-thirds of the deaths in the epidemic of 1793 to such errors in treatment, an opinion in which the modern critic can not concur. But he felt that he was the injured one in the controversies concerning bleeding and *ten and ten*.

In fact, he states, in a letter to his wife dated Oct. 24, 1793, that he "was publicly accused at every corner of having murdered the greatest part of the citizens who have died of the present disorder." In the same letter he speaks of going to New York and ending his days there rather than continuing in Philadelphia, where he saw nothing before him but strife and misery. Such was his discouragement at a time when he felt that he was making every sacrifice for his fellow-townsmen, even to the risk of life itself, and that he had discovered for them the only treatment for the disease of which they were dying by hundreds. In truth, it was Dr. Rush's plan to shun rather than to seek controversy. Within ten days of the date of the letter just referred to, he resigned from the College of Physicians of which nearly seven years before he had been one of the founders, because, according to Caldwell, of the abuse and persecution he had sustained from that body on account of his treatment of the epidemic disease by blood-letting and calomel. Some conflict of opinion on college affairs with the Rev. Dr. John Ewing, who was provost, led him to sever his membership with the Presbyterian Church of which Dr. Ewing was the minister. In this trait of character lies the explanation of the one difficult episode in Rush's career, his resignation of the office of Physician-General to the Army. This occurred in February, 1778, the terrible winter of Valley Forge. To the careful student of his life this act, which has been severely criticized, is perfectly intelligible. Worn out physically with the hardships of the service and thoroughly discouraged with political conditions, which appeared to him hopeless, he turned from a state of affairs in which he was useless, and, abandoning public life, resumed a career in which, as a private citizen practicing and teaching his profession, he was able to be of real service to his fellowmen. If, for a time, misled by an error of judgment, he listened to those who sought to gratify their personal ambition by changes in public policy or in the administration of the government, the delusion was of short duration.

Personal dislikes he had, like all men of strong nature, but that he lacked patriotism his whole career and his writings everywhere abundantly disprove. It is easier for us than for his contemporaries to realize how great was this error in judgment. That it was forgiven and forgotten during his life, leads the candid historian to believe that it may be condoned by a later generation. One thing about Rush that endears him to humanity is that he was intensely human. His most ardent panegyrist has not yet sought to endow him with superhuman qualities.

There is another side to the picture. Those who knew him best, best knew how to praise him.

Ninety-one years ago, almost to the day, Dr. David Ramsey, at the request of the Medical Society of South Carolina, delivered, in the Circular Church in Charleston, "An Eulogium Upon Benjamin Rush." The Society, on hearing of the death of Benjamin Rush, impressed with a high respect for his memory, resolved to go in mourning on the melancholy occasion. He had been the preceptor of sixty of its members, and Dr. Ramsey addressed an audience who knew Rush personally and closely. This discourse, which contains much information concerning Rush's life and attainments, has served as a source of many of the biographical sketches. It is dignified and temperate, but in the highest respect a tribute of affection and regard. He dwells on Rush's simple habits, his industry, his scientific spirit, his unselfish patriotism, his sincere piety. He lays proper stress on the part played by Rush in the founding of Dickinson College, "of which he may be called the father," and his founding of the Philadelphia Dispensary. In a word, Ramsey's address is in the highest sense a eulogium.

A few months later Dr. David Hosack of New York, in an introductory discourse, paid a tribute to the memory of the late Benjamin Rush in similar terms. This tribute lays especial stress on his charm of manner and the gracefulness of his conversation, adding that "few persons ever left his society without receiving instruction and expressing their astonishment at the perpetual stream of eloquence in which his thoughts were communicated."

---

* Ruschenberger.

Hear also Meigs in his charming reminiscences of the men who have served the Pennsylvania Hospital:

"We esteem the greatest name of the men who, in that now somewhat distant day, served in the Pennsylvania Hospital, was the name of Benjamin Rush, professor of the practice of medicine in the University of Pennsylvania.

"That eminent physician's renown was not founded alone on his grand career in the fatal epidemic of 1793, *or in like occurrences in years following.* It depended more on his surpassing and most captivating eloquence, on his great wisdom, his learning, and the inextinguishable zeal whose fire was not in the least assuaged at the time we attended on his last course of lectures, at that venerable and beautiful old age, which soon afterward let him down into an honored grave.

"May we not stop a moment just here, to express the wish and the hope that ere many years shall have elapsed the statue of that eminent American may find its appropriate plinth in some conspicuous part of the town whose very name is signally honored by his whole life and conversation."

Zimmerman wrote to Lettsom that Rush merited a statue not only from Philadelphia, but from all humanity.

His fame was such that he was honored with membership in nearly every medical and scientific society in his own country, and distinguished by many honors from similar organizations in Europe. He was created LL.D. by Yale College.

As a mark of respect for his medical character and writings, and especially for his accounts of the yellow fever, he received from the King of Prussia a medal; from the Queen of Etruria a gold medal; from the Emperor of Russia a costly diamond ring, and the thanks of the King of Spain. Two medals were struck in his honor at the United States Mint, of which he was so many years the treasurer. They have been described by Storer, from originals in his own collection. They have the same date, A(nno) MDCCCVIII, and are exceedingly rare.

Nearly a century has elapsed, and we, too, come to do his memory an honor long deferred. This monument, the gift of the profession, of which he was so illustrious a fellow, to the nation whose greatness he foresaw and predicted, bears on its pedestal four legends, commemorative of his learning, his patriotism, his sagacity as a specialist, and his greatness as a physician and as a man. Let us consider briefly each in turn.

"Studium sine calamo somnium"—"to study without the pen is to dream." Dr. Samuel Finley, of the West Nottingham Grammar School and later the President of Princeton College, was an excellent scholar and eminent teacher. Under his tuition and guidance Rush, as a lad, acquired the knowledge of classical literature and habits of study and observation which he continued to cultivate throughout life. During his brief stay at Princeton he was distinguished for his talents, his progress in his studies, and his eloquence as a speaker. His translation of the Aphorisms of Hippocrates into English while a student in Dr. Redman's office was evidence at once of his love of letters and his love of medicine. The literary habits early formed and always adhered to were in the highest degree methodical. His commonplace books were daily records of occurrences and comments on them. It was his practice in reading to mark any important fact or peculiar expression for future reference. He was a great annotator, and, like Gibbon, "he investigated with his pen always in his hand." Ramsey said of him: "He read much, but he thought more. His mind was constantly engrossed with at least one literary inquiry to which he devoted his undivided attention. To make himself master of that subject he read, he meditated, he conversed." He was much given to collateral reading, thus approaching the immediate subject of his thoughts from many different points of view. He entertained the quaint opinion that "ideas, whether acquired from books or by reflection, produce a plethora in the mind which can only be relieved by depletion from the pen or tongue"—an opinion entirely in harmony with his views concerning pathology.

His style is simple, lucid, direct. He is always concerned with the matter in hand rather than with the manner of presenting it. Now and then he is betrayed by the liveliness of his imagination into an odd or unusual expression, but with few exceptions his writings are dignified and graceful. They abound with an amiable egotism, more becoming in great than in little men to which they owe in part the personal charm and interest which his readers experience. In many respects the style of Rush compares most favorably with the best medical writings of his own or any subsequent period. To read one of his books arouses an interest that does not cease when all have been read. To come on the "Medical Inquiries and Observations" for the first time is to experience a feeling akin to that of Keats on reading Chapman's Homer:

> Then felt I like some searcher of the skies
> When a new planet swims into his ken.

The "Account of the Bilious Yellow Fever, as it appeared in Philadelphia in 1793," has been called the best history that was ever written of an epidemic. It attracted immediate attention throughout Europe, and was translated into three languages. His writings were numerous, and embraced nearly every subject of contemporaneous interest. Nothing but a faculty for close and accurate observation, the widest human sympathy and a sense of the importance of securing the largest audience for views which to him were of paramount importance could justify his addressing the public on such a diversity of subjects.

Samuel Jackson gives a list of Rush's publications arranged in four categories, and showing the state in which they were originally found in the book stores. They comprise: 1. Medical Inquiries and Observations, the Histories of the Yellow Fever Epidemics in Philadelphia, and other subjects purely medical. 2. The Introductory Lectures, of which there are sixteen; Medical Inquiries and Observations on Diseases of the Mind, and American Editions of Sydenham and other standard medical works, with annotations. 3. Essays, literary, moral, and philosophical, originally communicated to the periodicals of the day and subsequently collected and published in two volumes. 4. His political writings.

When we reflect that Rush was at every period of his life engaged in arduous and unsparing pursuits, holding public office, seeing many patients as practitioner and consultant, spending long hours in the Pennsylvania Hospital, bound by the fixed hours of the teacher, we marvel alike at the extraordinary range of his literary work, and even more at its abundance. He did the work of several men, and he did it well. What we call pleasure had no charm for him; of relaxation he had no need. His energy was indefatigable and his power of concentration phenomenal. His time was all his own, and he made the best use of it.

As a signer of the Declaration of Independence, we may well be proud of him. He had done much work in preparing the way for it, and was even more radical than his friends in urging its adoption. None knew better than he the stupendous responsibility of that utterance. There stands his name between the names of Robert Morris and Benjamin Franklin, a perpetual witness to his courage and patriotism. The parchment was engrossed before he was elected to the Congress, and, as Jackson says, he did not sign it because he was a member; he became a member in order that he might sign it.

The first American alienist, Mills, makes the statement that Rush and Ray are the two Americans who have done most for psychiatry, and adds that, valuable as more recent writings on the subject have been, and whatever the future may bring forth, these two are not likely soon to be displaced as the most striking figures in American psychologic medicine. Rush was no specialist in the modern sense in which we use this word. With him every branch of medicine was for the time being a specialty. His methods of study, and the limited range of medicine in his day made this possible, and hygiene, military medicine, the fevers, diseases of the chest, diseases of children, therapeutics, climatology, and epidemiology engaged his attention in turn, and became the subject of special communications to his fellow-practitioners and the public at large. As he grew older the subject of lunacy and the proper treatment of the insane more and more engaged his thoughts. His well-known letter to the managers of the Pennsylvania Hospital against confining the lunatics in cells was written in 1789; his carefully prepared communication suggesting many improvements in their treatment, in 1810; his Medical Inquiry and Observations on Diseases of the Mind first appeared in 1812, a few months before his death. This treatise is full of instruction and originality, and owes much of its value to facts and cases drawn from the author's own experience. He recognizes the physical, mental and moral causes of insanity, exhibits its many forms and phases by the graphic relation of cases, gives an ingenious and original classification of insanity, elaborates the principles of diagnosis and prognosis, and enlarges on its management and treatment. He regarded disorders of the mind as forming part of the general course of medicine, and, as indicated in a published syllabus, insisted on their being placed in the curriculum—a plan long neglected in the medical schools, but now being generally adopted. He was also nearly a century in advance of his time in suggesting detached cottages for the care of convalescents. He also advocated the founding of institutions for the care of dipsomaniacs. As a specialist in diseases of the mind, Dr. Rush forms a remarkable and most impressive historical figure.

As a physician and philanthropist Dr. Rush occupied during his life the central place on the stage of American medicine. Nor has the flight of time altered his position. It is no disparagement to any of his successors to repeat that in the history of American medicine he still holds that conspicuous position.

As a physician he was all that the best education of his day, the finest personal traits, a noble character, an exhaustless energy, ability of the highest order, and a child-like piety and faith could make him. We can not measure his practice by ours, for old things have passed away and all things have become new. But we must grant him the courage of his convictions. If his premises had been true—alas! the if—his conclusions would have been inevitable and his practice logically correct. The Defence of Blood-letting makes us shudder. To him the facts amounted to a demonstration of the curative power of that sanguinary measure; to us they only show the enormous resistance of certain organisms to depletion. His therapeutic optimism was incredible. It was based on a pathologic system that was as fantastic as it was misleading. Groping in the dark, he struggled toward the light. The traditions misled him, but his own powers of observation set his feet on the right way. He was the father of experimental medicine in America. Witness the experiments on which his thesis was based and the curious investigations in regard to the action of certain substances on worms. There was in him something of that prescience that belongs to genius. He was led by a consideration of the accounts of the "exemption from the pains of child-bearing that are recorded of the women in the Brazils, Calabria, and some parts of Africa, and the small degrees of it which are felt by the Turkish women. . . . to believe that pain does not accompany child-bearing by an immutable decree of Heaven," and expressed a hope "that a medicine would be discovered that should suspend sensibility altogether and leave irritability or the power of motion unimpaired, and thereby destroy labor-pains altogether." The reasonableness of this hope, based as it was on moral evidence, was such that it amounted to faith. He approached the subject in a spirit of profound reverence, on account of the authority on which the popular notion of the penal character of the travail of childbirth, including of necessity physical pain, was supposed to rest. His attitude in this matter showed courageous disregard of ecclesiastical and popular opinion, the most profound human sympathy, and prophetic vision in anticipating by nearly fifty years general anesthesia in parturition.

If we wish to know what he was as a practitioner, let us turn to the "Old Family Letters"* written to his wife during the awful epidemic of 1793. They are too sacred to be published even after all these years. They show us the man, Rush, tender, gentle, broken-hearted at the awful calamity that had befallen his people; the physician, quick to go to the relief of rich and poor alike, fighting a losing fight with his wretched lancet and ten and ten, and never faltering because of the faith that was in him, inspiring the citizens, firing his pupils, though they died, and winning back his deserting colleagues; the hero, who would not, come what may, desert his post.

When the published account of that fearful period became known "all Europe was astonished at his novelty and bold decision, his unprecedented sagacity and judgment." The older among us have had some experience in skirmishes against epidemic diseases. Think of the heroism of the leader in a great fight like that in Philadelphia in 1793! And the fever! It is all very simple now, looking back on it from the vantage-ground of recent years. But the awful mystery and horror of it then!

After what has been said, is it necessary to speak of philanthropy? Is not his love of his fellow-men set forth in every word that I have spoken of him, on every page that he wrote? Rush has been compared with the great men in medicine. He has been called the American Hippocrates, the American Sydenham, and likened to Fothergill and to Boerhaave, the great teacher of Leyden.

---

* Privately printed.

None of these comparisons is fair to him. He was great in his own right. Richardson calls him "one of the most original and powerful men whom medicine has ever claimed for a son." He was the first Great American Physician.

To you, Honored Representative of the Nation, I, for the moment the representative of the medical profession, present this monument. Accept it as a token of the good will of our guild toward your people, our brothers, and as an enduring memorial of one who exemplifies in an unusual degree the ancient maxim, *"Dii laboribus omnia vendunt."*

THE DEVELOPMENTAL DEFECTS OF THE SKIN AND THEIR MALIGNANT GROWTHS.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON CUTANEOUS MEDICINE AND SURGERY, AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT ATLANTIC CITY, JUNE 7-10, 1904.

HENRY G. ANTHONY, M.D.
Professor of Skin and Venereal Diseases, Chicago Policlinic.
CHICAGO.

The term nevus, originally used by the laity, has been so thoroughly adopted into medical nomenclature to designate congenital blemishes of the skin that any attempt to change or even modify the meaning of the word can only result in confusion, and yet that is the present tendency in dermatology. Unna[1] says that it is questionable if nevus linearis will permanently maintain its place among the nevi because of the rapid development which it frequently exhibits in extrauterine life.

Postnatal development of a lesion of intrauterine origin is a striking clinical fact, but it is hardly of sufficient importance to form the basis of classification. There are few malformations of the skin which may not grow rapidly or even present themselves clinically for the first time in adult life.

French authorities use the expression nevus tardive to designate the late developing nevus. Though well understood in France, I have known this expression to cause misunderstanding in our country.

In England, Crocker[2] says the word nevus is applied only to vascular growths, and he designates neoplasms of intrauterine origin by the term "embryogenic growths."

The *Pratique Dermatologique* adopts Brocq's definition, "a nevus is any circumscribed deformity of the skin." Under this definition adenoma sebaceum is a nevus.

In my opinion the word nevus should be used simply as a term of clinical convenience to designate any mark on the skin present at birth or developing shortly after birth regardless of its histologic structure and without any attempt at scientific accuracy.

This is still the accepted use of the word in other branches of medicine and it should continue to be employed in this sense in dermatology.

Any expansion of the meaning of the word in dermatology will cause as much confusion as does the double meaning of the word tubercle.

As a term to designate deep-seated deposits, the word nodule should be employed, and we should use the expressions nodular syphilide and nodular leprosy rather than call these lesions tubercular syphilide and tubercular leprosy.

To avoid all confusion of nomenclature and misuse of the word nevus, it would be advantageous to employ the expression developmental defects of the skin, to designate all abnormal conditions of intrauterine origin which are not due to disease of the fetus.

There are two classes of cases, misplacements and anomalies of development. Under the latter class we would recognize anomalies of hair and nails, of keratinization, of pigmentation, of blood vessels, of fibrous tissue and some other forms.

THE CAUSES OF DEVELOPMENTAL DEFECTS OF THE SKIN.

The causes of defective development are probably multiple. At the present state of our knowledge there are two which should be carefully sought for in each and every case that passes our observation: heredity and the toxins of the chronic infectious diseases. "Like begets like." A peculiarity of development existing in one generation of a family is frequently observed in succeeding generations. I have observed three generations of a family in which a tuft of hair like a mane grew over the seventh cervical vertebra with no alteration of the skin developing in each instance at the time of puberty. It was present in the grandfather, in his three sons, and one of the sons having four children, in each of the children.

Peculiarities of development in lower animals may also be observed in succeeding generations. The Holland belted cattle illustrate my meaning. They are a breed of cattle which resemble the Holstein in general build, but differ in the fact that they have a broad black belt extending around the body. This black belt once established, the animals breed true, and it is regularly present in the offspring.

One of the most remarkable examples of the manner in which a developmental defect may become a racial characteristic to be found in the animal kingdom is that observed in Polish chickens, in which a greater part of the brain is an encephalocele contained in a vesicular-like bony protuberance of the skull. Aldroini[3] mentioned these fowl in 1600, at which time the deformity does not appear to have developed into a breed characteristic.

THE TOXINS OF THE CHRONIC INFECTIOUS DISEASES.

Charrin and Gley,[4] wishing to study the effect which the toxins of chronic infectious diseases would have on the offspring when administered to the parent animal, subjected rabbits, both male and female, to the influence of such toxins, and after a variable length of time bred the animals, sometimes mating a healthy buck with a doe which had been subjected to toxins, sometimes reversing the mating and again breeding animals both of which had passed under the influence of toxins.

The results were most striking and excited great interest in France, especially among dermatologists.

Barthelmy[5] has tried to show that the toxins of syphilis cause various stigmata such as nevi and all kinds of imperfect development in the third generation.

Since my attention has been directed to this subject I have observed a number of cases in which this theory could be invoked, and I have seen some in which no such explanation could be offered; the subject is worthy of consideration.

THE DISPLACEMENTS.

The developmental defects of the skin which are of greatest importance at the present time are those which are formed by the glandular elements of the skin and the pigmentary mole. These conditions have been more discussed by dermatologists during the past few years than almost any subject of cutaneous medicine.

According to Unna pigmentary moles are cell inclusions. Crocker describes adenoma sebaceum as a congenital overgrowth of an adenomatous character, developing from embryonic remnants in the skin. He has seen them develop in adult life and he finds them not uncommonly in the inmates of idiot asylums.

Hydradenome cruptive is described as a nevus in the *Pratique Dermatologique* and most authors describe benign cystic epithelioma as belonging to this disease. Toeroek[6] says that he formerly shared this opinion, but since studying sections obtained from Brooks' case he has concluded that benign cystic epithelioma should be held separate and apart from hydradenoma.

From a study of slides from Fordyce's case I agree with Toeroek. I see no reason to believe that the growth is derived from the sweat glands. The opinion originally expressed by Fordyce that the cells are derived from the rete I believe to be correct. That there should be any controversy on this subject is due to the fact that hydradenoma may clinically resemble benign cystic epithelioma very closely and that those who have studied hydradenoma microscopically have not had slides from benign cystic epithelioma for comparison.

In my opinion these conditions are one and all of them displaced cells, the displacement occurring in embryonic life, carrying with it different parts of the skin in different cases. In one case the displaced cells are chiefly derived from sebaceous glands and develop into adenoma sebaceum in postnatal life. In another case the displaced cells are mostly sweat gland epithelium which will form hydradenoma eruptive. Benign cystic epithelioma results from the displacement of cells of the rete.

The pigmentary mole, which is the most common of all displacements, contains cells which are of an embryonic type. These conditions are in every way the equivalent of dermoid cyst of the ovary, provided we agree with Marchand that dermoid cyst of the ovary is a displaceent. It develops in adult life; it may contain teeth, hair or cholesterin and its walls may be lined with a membrane containing dilated sebaceous glands; one or the other accessory organs of the skin preponderating.

THE PIGMENTARY MOLE.

Clinically this malformation of the skin varies within wide limits, from the simple stain remaining unchanged throughout life, to the mammillated plaque of the covered regions of the body or the hemispherical pedunculated pea-sized tumor of the face often having a growth of a few hairs. As a rule it exhibits a gradual increase in size and frequently a decrease in pigmentation as the years go by.

Histologically they are all of the same structure, containing displaced connective tissue, displaced epithelioid cells, and displaced hairs with more or less abnormal pigmentation. The variation in the clinical symptoms is due to the amount of tissue displaced and to the preponderance of one element of displacement over another. A simple stain of the skin contains only a small cluster of epithelioid cells, while a mammillated plaque contains large perpendicular strands of epithelioid cells alternating with strands of coarse connective tissue.

The pigmentation differs widely in different cases; it is like that of the negro, present in the form of fine grains in the deep layers of the rete, but it has an uneven distribution.

THE EPITHELIOID CELLS OF THE PIGMENTARY MOLE.

After ten years of discussion regarding the nature of these cells we may state, that the older opinions that they are the cells of lymphatic channels, endothelial cells, etc., have now few supporters and that it is the opinion of most investigators that they are either embryonic connective tissue cells, as Riehl and Rieche believe, or else they are epithelium cells, as Unna and his followers, who are in the majority, believe.

According to Unna's theory the rete pegs grow downward into the corium about as they do in a wart, and clusters of cells become detached from their ends and undergo a metaplasia by which they lose their prickers and revert to the embryonic type, and furthermore, this cleavage of cells in clusters and metaplasia occurs not only *in embryo*, but may even be seen occurring in infancy. Just as drops of water drip from the point of an icicle so do these clusters of cells become more slowly detached from the ends of the rete pegs.

That clusters of cells actually become detached from the rete pegs he determined by serial sections, and his findings have been substantiated by Gilchrist, Schueber, Abesser and others, while on the other hand Ribbert and Rieche[7] find that no separation occurs and they believe that the peculiar figures of the rete pegs which at first view appear to be clusters of cells detached, undetached and in process of being detached from the rete pegs, are produced by oblique sectioning and by outward pressure. Rieche finds that the rete figures occur in nevi of adult life even in the sixtieth year, and he finds no separation in serial sections.

Abesser,[8] who accepts Unna's theory, also finds them in adult life. I have found them as late as in the fortieth year of life, and I agree with Rieche that no detachment of cells occurs.

Unna has observed these same figures in certain cases of fibroma molluscum and he argues that their presence shows that such cases are really cases of nevus. Whitfield[9] finds them in nevocarcinoma even more frequently than in the nevus.

A microscopic finding is one thing, an interpretation of the finding is another thing, and these two things are to be considered separate. Before any attempt is made to elucidate a microscopic observation, every possibility of diagnosis should be considered and that has not been done in the study of this condition.

Unna's theory depends entirely on the interpretation of the figures of the rete pegs, and as I am convinced that no separation occurs, I maintain that his theory should be discarded.

There is no doubt in my mind that the displacement occurred and was completed in early embryonic life. In other words, the pigmentary mole is to be explained by the Cohnheim theory and not by the Unna theory.

Whether the displaced cells are epithelium or connective tissue can not be determined at the present state of our knowledge. Unna gives the reasons for believing that they are epithelium and Rieche the reasons for believing that they are connective tissue.

If Kromayer's[10] theory of desmisphasia is accepted as correct, the question is of little importance, inasmuch as a connective tissue cell may be transformed into an epithelium cell.

THE MALIGNANT GROWTHS WHICH DEVELOP IN DISPLACEMENTS.

Hallopeau and Derier[11] have reported a case of hydradenoma complicated with epithelioma, and Audry has reported a second similar case.

An epithelioma developed in Dyer's case of benign cystic epithelioma and also in White's case. Epithelioma may appear in moles and occasionally a spindle-cell sarcoma, but the tumor of greatest interest which develops in moles is the melanotic small round-cell growth which is now called nevocarcinoma.

The melanotic pigmentation which is present in greater or less amount in these growths is one of their most characteristic features. Clinically melanosis may involve extensive areas of cutaneous surface and be present for a considerable length of time before the tumor develops sufficiently to be recognized. It may spread into healthy tissue surrounding the tumor; it may affect the skin in large plaques at a distance from the tumor, as in Bamberger's case, or involving the lymphatic vessels, it may produce a lymphangitis of a bluish color extending from the neoplasm to adjacent lymphatic glands.

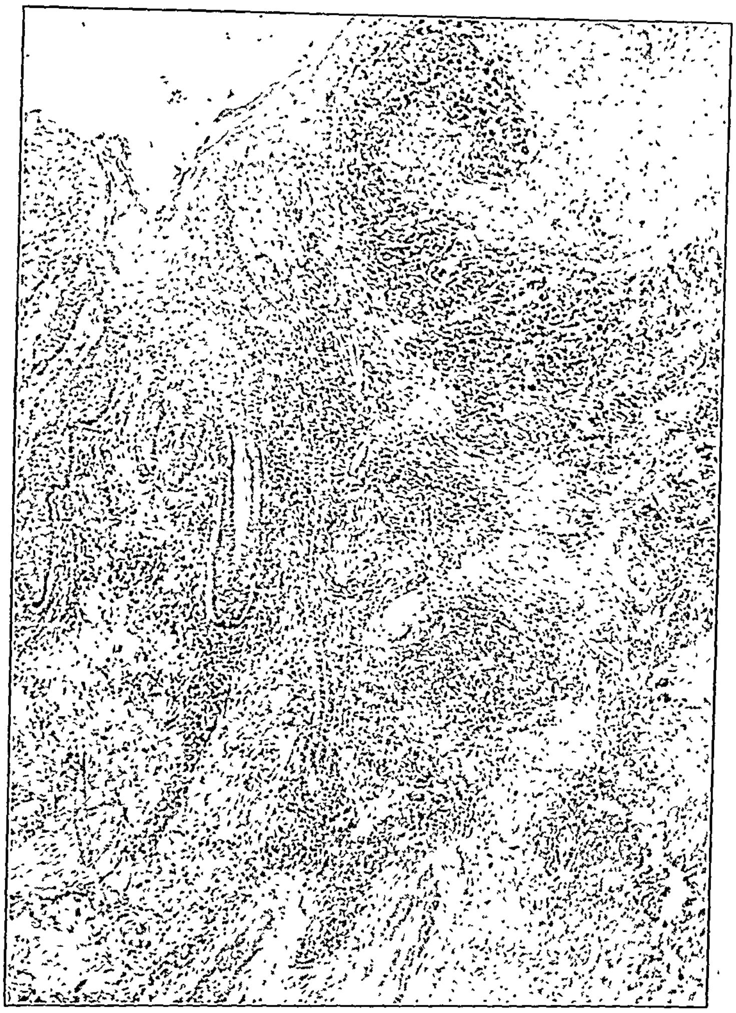

Fig. 1.—(Low power.) Simplest form of nevomelanoma. Epithelioma of the epidermis and nevomelanoma with its accompanying pigment in the derma.

Eve[12] has recently reported an important series of cases which show that melanosis may occur in the skin or visceral organs, or metastatic tumors may develop and on examination lymphatic glands will be found in some part of the body as the first sign of disease and in close proximity to a mole which shows no change.

It is not uncommon for the disease to start from a mole which shows no symptoms of the disease. The case reported by Hanocque[13] in 1868 as a case of primary melanosarcoma of the axillary glands was possibly of this category. Melanosis is not always a sign of malignancy; it exists normally in the iris and some other parts of the body.

Ullman[14] presented a case of cavernous angiomata of the face before the Vienna Dermatological Society which exhibited black pigmentation. In discussion Kaposi stated that he could not conceive of such tumors being present in the absence of sarcoma, and he would advise that a very thorough search be made for the presence of sarcoma cells. His suggestion was followed with negative result; the patient died of septic pneumonia after being under observation for six years, and a careful postmortem failed to reveal the presence of sarcoma in any part of the body.

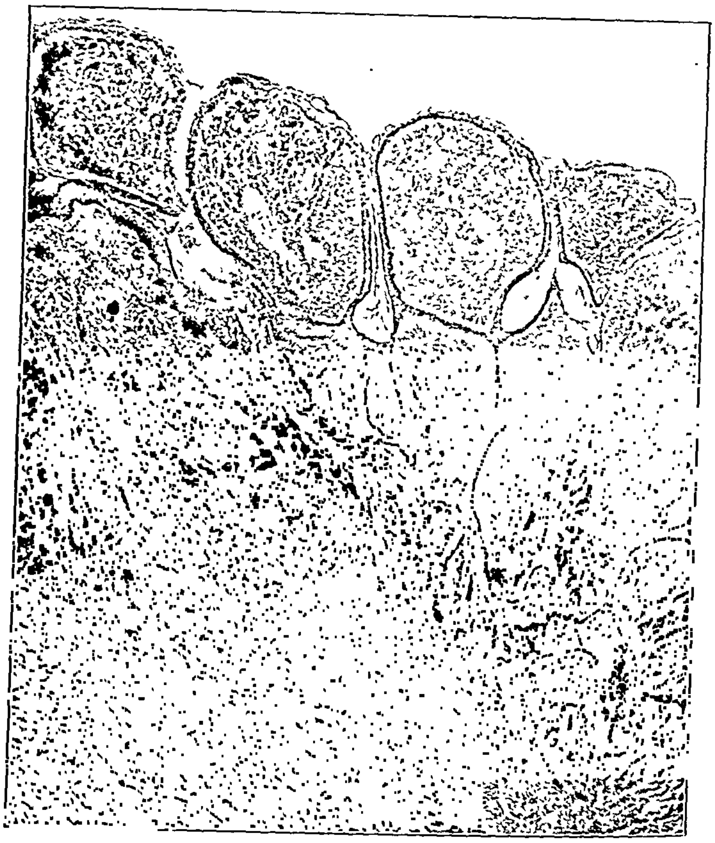

Fig. 2.—(Low power.) Honey-comb-formed nevomelanoma. The nevomelanoma has invaded the epithelioma, producing the honey-combed appearance. The epithelioma represents the comb, and the nevomelanoma and its accompanying pigmentation represents the honey.

Nervous exhaustion or shock may produce melanotic pigmentation. Bark[15] has reported the case of a woman, 53 years old, who, receiving a severe mental shock caused by the suicide of her daughter, developed generalized melanoderma which lasted two years.

I find this difference between the pigmentation of the nevus and that of the nevocarcinoma; the pigmentation of the nevus is associated with the epithelium of the rete, the hair root or the glandular epithelium, while that of the tumor is associated with the epithelioid cells.

NEVOMELANOMA.

Schalek[16] bases his opinion that the malignant growths which develop in nevi are carcinomatous mostly on a study of the chromatophores which have now lost their importance in determining the character of these growths. They are probably leucocytes transporting the superabundance of pigment which the tissues produce to the lymphatics and blood vessels, thereby causing melanemia and melanuria, which are essential features of the disease.

Ravogli[17] especially emphasizes the alveolar arrangement and the relation between the epithelium cells and the pigment.

Green[18] says that the sarcomatous nature of angiosarcoma which has an alveolar arrangement can not be questioned and that the distribution of the pigment in these tumors is not of such a kind as to indicate that the epithelioid cells were derived from the rete. I agree with Bland Sutton[19] that the alveolar arrangement is simply an exaggeration of the normal arrangement of the nevus.

Waldeyer, whose opinion carries greater weight with it than that of anyone else who has accepted Unna's theory, bases his acceptation on an inspection of Unna's slides without showing that he has studied the effect of outward pressure, and the same criticism may be offered of most of the others who follow Unna.

For the material which enabled me to study these tumors I am indebted to Professor Herzog of the Chicago Policlinic, and to Professors Hektoen and Le Count for placing at my disposition the splendid material contained in the laboratory of Rush Medical College.

The *Pratique Dermatologique* says "that the characteristic which distinguishes this tumor from all other cancers is that in the structure of its elements and in the texture of its tissue, it is intermediary between a carcinoma and a sarcoma."

That the tumor is derived from the epithelioid cell of the nevus there can be no doubt. Wherever we find one of these tumors forming in the epithelioid cells of the corium we know that an epithelioma like down growth of the rete may be seen in the immediate vicinity (Fig. 1).

This was the finding in Gilchrist's,[20] Waelsch's and Minne's cases and in all the cases examined by me. The microscopic picture which the growth presents depends on the manner in which these two tumors, developing in close proximity, combine.

Waelsch[21] published his cases to demonstrate the fact that the tumor does invade the epidermis. He is quite correct, but he overlooked the important fact that when it does it pushes the epithelium cells aside. The cells of the tumor never mingle with the cells of the epidermis; one can always distinguish the tumor cells with the accompanying pigmentation from the epithelium cells. In some cases, through the development of the tumor cells in the epidermis, a honeycomb-formed tumor is produced

As is shown in Fig. 2 the epidermis cells form the comb and the tumor cells with the pigmentation represent the honey. In cases where the epithelium cells are rapidly proliferated and imperfectly formed the growth is like a venereal wart, consisting almost entirely of scrolls of epithelium cells with small interspaces between the scrolls which contain the tumor cells and their pigment (Fig. 3). In this class of cases what is tumor cell and what is epithelium cell can always be determined.

This fact that we can distinguish the tumor cell from the epithelium cell, and the fact that the tumor cell always pushes the epithelium cell aside, are, in my opinion, important in determining *the classification of this* tumor.

Where a metastasis occurs to a neighboring lymphatic gland or develops in a visceral organ, it is the tumor cell and its pigmentation and not the epithelioma, which is transported.

Green says that the tumor of the choroid which has always been looked on as sarcoma and the formation of which has always been considered to be connective tissue, corresponds fully in architectural structure with the nevomelanoma.

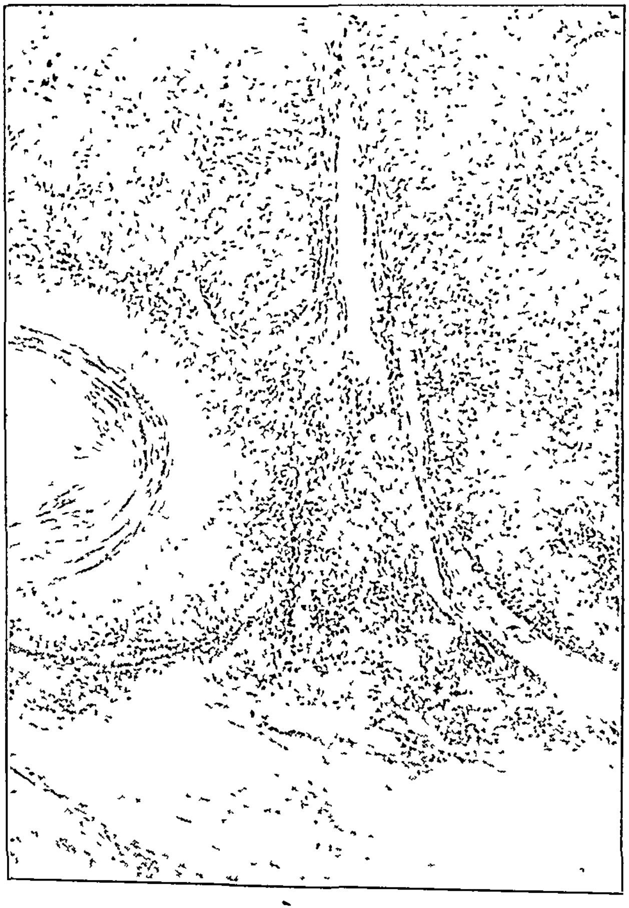

Fig 3—(Low power) Venereal wart like form of nevomelanoma. The nevomelanoma, with its accompanying pigmentation has invaded the interspaces of the epithelioma epithelial pearl

Le Count (personal communication) states that given a metastatic growth of the skin, one can not determine whether the primary tumor was located in the skin or in the choroid, inasmuch as the same form, size and character of cell, the same pigmentation, and the same alveolar structure is present. The primary tumor showing the same characteristics could be distinguished by anatomic landmarks such as an attached piece of normal skin. Anyone with the necessary material at his disposal may convince himself that this statement is correct

Gensberg and almost all other oculists believe that the choroid tumor is a sarcoma.

There is no tumor classified to-day as carcinoma which differs from all other forms as much as does this form,

The rodent ulcer is a distinct variety of epithelioma until it reaches the terminal stage, when it assumes the general characteristics of all other malignant epithelium neoplasms; not so with nevocarcinoma; it presents special clinical and histologic characteristics from beginning to end.

Birch-Hirschfeld[22] says: "In regard to the clinical features of these tumors we will state that the melanosarcoma, as is well known, shows a high degree of malignancy, which is not due to a tendency to local destruction of the growth, as in carcinoma, neither is it due to toxemia, but rather to the multiple development of metastatic tumors which appear in the terminal stage of the disease. This disposition to the formation of embolic metastasis must be considered the essential basis of the clinical malignancy of the sarcoma."

From what we have said it will be seen that this tumor differs both clinically and in its histopathology from carcinoma. It therefore should not be classified as a carcinoma. It develops in displaced embryonic tissue, which is probably of epithelium origin and it should be classified separate and apart from all other malignant growths and called nevomelanoma.

THE VALUE OF SYMMETRY IN EDUCATION AND CHARACTER.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON STOMATOLOGY AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT ATLANTIC CITY, JUNE 7-10, 1904.

GEORGE F. EAMES, M.D.
BOSTON.

In the contemplation of any subject, be it animate or inanimate, the pleasure and satisfaction derived therefrom is dependent in a great degree on its symmetrical proportions; indeed, asymmetry, as seen in many objects, and especially in the human form, is a positive disfigurement, and is often repulsive.

But symmetry as I wish to discuss it will be considered in connection with the mind and soul. It will be noted at once that lack of symmetry in the mind is not so readily observed as a similar condition of the body, although they are vastly more common, and the deviations from what might be considered typical in the former would be altogether hideous if the same disproportion were exhibited in the physical system. Imagine a nose, which by a slight aberration of development has continued to grow until it is twelve inches long; or one eye eight inches in diameter and the other a mere pinhole! Such an extreme in physical deformity has probably never been known, yet similar disproportions, or greater, may easily be conceived to exist in the different powers of the mind. In the dental profession we should not expect to find excessive abnormalities or great deficiencies in intellect, but there are many indications that the majority of practitioners might develop their mechanical and intellectual powers in certain directions with great benefit to themselves and patients, and everlasting good to all people over whom they have any influence. This means that there are many defects in symmetry to be observed among dentists, and even among stomatologists.

While some defects may be found in the best of men, those which we have now under consideration are such that they, in many instances, ruin the man as a practitioner, and in nearly all the other cases mar his brilliancy and seriously handicap his professional progress. Take, for example, the life of the late P. D. Armour, the great capitalist of Chicago; his strict devotion to business, at the expense of all social life and entertainment, and his abstemious habits were still kept up even after his financial worth was counted by millions. While his business ability was increasing, other faculties of mind and heart were weakening, and when this hypertrophic condition, in the shape of an enormously enlarged business capacity, became pathologic, and the discrepancy between this and other bodily and mental functions became so great that he began to suffer from the strain, he was urged to rest and go to Europe. He went, but he had lost all capacity for the enjoyment of travel and change of scene, and he died in the harness which he had himself constructed. The following quotation from Charles Robert Darwin shows still further the effect of asymmetrical development:

> I have said that in one respect my mind has changed during the last twenty or thirty years. Up to the age of thirty, or beyond it, poetry of many kinds, such as the work of Milton, Gray, Byron, Wordsworth, Coleridge and Shelly, gave me great pleasure, and even as a schoolboy I took great delight in Shakespeare, especially in the historical plays. I have also said that formerly pictures gave me considerable pleasure, and music very great delight. But now for many years I can not endure to read a line of poetry. I have tried lately to read Shakespeare, and found it so intolerably dull that it nauseated me. I have also almost lost my taste for pictures or music. . . . This curious and lamentable loss of the higher esthetic tastes is all the odder, as books on history, biographies and travels (independently of any scientific facts which they may contain), and essays on all sorts of subjects, interest me as much as ever they did. . . . Why this should have caused the atrophy of that part of the brain alone on which the higher tastes depend I can not conceive. . . . If I had to live my life over again, I would make it a rule to read some poetry and listen to some music at least once every week, for perhaps the parts of my brain now atrophied would have thus been kept active through use. The loss of these tastes is a loss of happiness, and may possibly be injurious to the intellect, and more probably to the moral character, by enfeebling the emotional part of our nature.

Prof. Charles Eliot Norton says: "Whatever your occupation may be, and however crowded your hours with affairs, do not fail to secure at least a few minutes every day for refreshment of your inner life with a bit of poetry."

A few weeks ago I met a physician in the suburbs of Boston. He was apparently taking a walk for pleasure, and was observing some birds by the way. My first thought was one of surprise that this physician, in full practice, the author of a large work and in many ways one who must meet numerous demands, could and would find the time for such a purpose, but a moment's reflection convinced me that such use of time was very wise and judicious—that it was necessary, not alone for diversion and recreation, but that it served to cultivate the mind, to broaden the view and to render more sensitive and acute the artistic and moral sense. In many other ways a study of the lower animals increases, by comparison, our knowledge of the higher; and this is, as we well know, of essential value to the physician. It is a grave mistake to neglect the cultivation of the artistic and esthetic sides of our nature, of a love of the beautiful, of sympathetic feelings and of all that is delicate and refined, whether one is fitting to become a physician, a general, or a special surgeon.

Away with the idea that the surgeon needs no feelings of delicacy and sympathy; that, devoid of all sense of feeling, he cuts across nerve and artery, or that he administers an anesthetic which suspends nearly all the functions of life without giving a thought to the real condition in which he places his patient—without feeling the full weight of responsibility in holding a precious life in his hands! It is true that a surgeon should not allow his feelings—his emotions—to be uppermost when he is performing an operation. To all appearance he must be devoid of sensibility, and even sympathy—yet the world knows that the greatest delicacy of perception, the keenest appreciation of possible pain are a part of his equipment, and that it is only the well-being of the patient which demands apparent indifference to suffering. If he can not, for the time at least, lock up his "feelings" so that they will disturb neither his patient nor himself, he loses something of his dexterity and physical poise. But sensitiveness—mental as well as physical—is a very important characteristic of a great physician, and this same sensitiveness is cultivated or lessened, as the case may be, by a man's daily living and his attitude toward life. He may harden and blunt his perceptions as he may, dull his tools if he will, but good work demands the keenest edge of which he is capable.

---

[22] Birch-Hirschfeld: Real-encyclopædie der Gesammte Heilkunde, vol. xxi, p. 179.

The practical and important issue before us, in view of the conditions to which reference has just been made, is this: What are the more important defects in our professional life, and what are the remedies? The first consideration in seeking to correct a diseased or any undesirable condition is to discover the cause, and here it is to be sought in the early years of child-life, although, indeed, causes may exist generations before. Manifestly, the suitable preparation of body and mind for the duties of life may be included in the broad term, education. Asymmetry due to lack of development, then, of the body or mind is due to faulty education. Many of our college graduates are like statues, carved to be placed in a frieze. The side toward the public gaze defies criticism, but the rest is of rough, unhewn stone.

It is evident that life is too short to pursue studies in every direction available at the present time, therefore a choice must be made; on this choice may hang future success or failure, and to it we may look for the cause of many deficiencies in development of both body and mind. The writer believes that much is taught in all departments of education which has no vital and practical value in the life work to come. With innumerable subjects for study, with the many subdivisions of these subjects and the almost unlimited extent to which they may be pursued, the great need is shown of weeding out, and also the serious difficulty of doing so. Everything which is taught at the present time has a certain value, and one reluctantly strikes out of the list anything which is worth while, but it is a choice between greater and lesser values. From early childhood it should become a matter for serious consideration, not only as to what shall be taught, but also as to what needs curbing, and what should be strengthened. Mere intellect, as some one has said, is as hard hearted and as heart hardening as mere sense. We need to remember this in our schemes of education. A little child, instead of being confined in a room for hours, where he is taught the alphabet or spelling, would be far better off were he out in the fresh air and sunlight, becoming familiar with the colors and flowers and the facts of nature.

Later in life, in the preparatory schools, no one will question that mathematics is an essential item in the curriculum, yet even here we may make an improvement in the old methods by substituting something more useful and practical for the higher mathematics, leaving these until later, or until the life work is chosen.

The writer has in his school days spent much time over mathematical problems or catch-traps which had no value beyond the discipline and exercise which it gave the mind, and he believes that something else might have been substituted which would have given the necessary discipline and exercise, and at the same time would have educated me in a useful and practical way. On the other hand, overindulgent parents and unthinking teachers may allow a child to follow his bent too closely, and the very danger is precipitated which we wish to avoid. In order to produce a symmetrical figure, the pedestal or foundation must be strong and well rounded, so that however elaborate the decoration of the capital or head of the column may be, there shall be no incongruity between it and its base. A school course which should fitly train mind, heart and body in the right degree would be the ideal one.

It would seem to be a wise procedure if exercises were introduced at an early age with the object of ascertaining the prominent characteristics inherent in each child; for instance, even in kindergarten life, a talent, or the ability to do one thing better than another, is often shown, as are the inventive and constructive powers. Equal attention should, of course, be given to finding out and strengthening weak points. This, if systematically carried out during school life, and a record made and kept for future reference, would be valuable. For example, a young man, with the help of his friends, wishes to determine in what direction his life work shall be. In coming to this decision he not only considers what he thinks he would like to do, what he is most interested in, and how he could obtain the most money, but he should by no means neglect to take into consideration the direction in which his greatest talents lie, the things which he has done with the most marked ability, the work which by nature he is best adapted to do. For this purpose recourse may be had to his school record, which is on file at the schools which he has attended. This record will show, from child life up, the individual's proficiency in drawing and other work which shows artistic ability, also the student's aptness in a mechanical and manipulative way. The inventive powers are often shown even in kindergarten life in the various shapes and ways in which blocks may be arranged, etc.

These and other items of the student's school record should be of great assistance in the choice of a vocation. To take up the life work to which one is best adapted, means the greatest possible usefulness to mankind, the happiest and most harmonious life and the most symmetrical growth. Again, this system of recording should be of great service to those who have charge of the entrance of candidates into colleges of dentistry, law, medicine, and others. This record should stand not only for the applicant's ability as a student, but for his special adaptability to a given profession, and no other entrance examination should be needed. Why should any second examination be made if the first is satisfactory? Is it not a declaration that the first is not to be depended on if the record is made? What a comment on the learning and teaching ability of our esteemed professors in the dental colleges, that their graduates with a diploma bearing their signature and the seal of the college should fail to satisfy a state board of examiners, or be debarred practice in another state! Surely, there is a great lack of symmetry in the results of our modern college work; if not, then the work of the state board of examiners is unnecessary, for no one should be allowed to practice as a stomatologist without a diploma, and that diploma should stand as the best passport to practice. Regarding the standard of entrance to colleges of stomatology, it should undoubtedly be high, but even this may be overdone and ill-advised. To the writer's knowledge, many who have entered the dental college as graduates of a high school have been among the worst specimens of graduate practitioners, and far below in quality those who had been received without having had such a course. Graduation from a high school as a minimum standard may be used as a basis, but this alone is not sufficient. If symmetry be wanting, the high school graduate is of poor promise and his entrance to the dental college should be postponed or discouraged. If a degree is required for entrance, and it undoubtedly should be, still it is necessary to look for other qualifications, especially if degrees may still be obtained from some sources for money and while it shows nothing of the candidate's manipulative dexterity.

By lack of symmetry in such cases is meant a deficiency in mechanical ability or literary culture, for instance, to such an extent that it would be unwise to receive the candidate. On the other hand, a young student who, for some good reason, has not graduated from the high school, may have such a symmetrical record as far as he has gone, and shows such qualifications of promise, that it would be very unwise to reject him. Of course, desirable candidates do not need an entrance examination; they do not need a four years' course or one of two years; they would reach the high places in the profession in spite of the entrance examination and the college courses, and they are so well endowed, mentally and physically, that they are able to decide as to their own fitness for a certain profession. Their own desire and ambition is for the best things, and they are not limited by years in a college; they would even get on without the college, and no ordinary hindrance could prevent their success. A friend of mine, a physician, now one of my listeners, was with me a few years ago in the Tower of London, and we stood on the spot where Anne Boleyn, Lady Jane Grey and Katherine Howard were beheaded. My friend the doctor remarked: "If they'd let them alone they would have died themselves, long ago." So with the most desirable men of our profession; they are such that if we let them alone they will go on with their professional development without regulations as to entrance standards and length of college courses that we spend so much time in talking about. The problem is to keep out incompetents and the unworthy, even if they may have in a fashion "gone through" some school or college with the required standard. We might have a ten-year course for Jack Blunthead, and he would still be unfit, while Joseph Sharp has passed all the requirements of the ordinary graduate in two years. A matter of years alone, or even the administration of thyroid extract, will not always qualify, and there is nothing that will qualify if there be not inherent in the individual the incentive and the genius to succeed. Quality, not quantity, is the essential requirement, and if this be attained, what can it matter whether the student has achieved it in one year or four, although the preference should be given to the one-year man? Therefore, when it is proposed to extend the dental course to four years, I am opposed to it; but this should not, by any means, convey the impression that anything but the highest standard is advocated.

Time is too precious to compel such men as we have pronounced worthy to enter the dental college, to give four years of their life in it. Three years is enough time to give to that part of the student life which is spent within the college walls. To all right-minded graduates, the end of the college course is but the beginning of studentship in earnest. Out of college the student, now also a practitioner, has entire management of his education and the development of his talents, and his success and future degree of symmetry, the nearness with which he comes to the finished product in man, is limited only by himself.

Among practitioners many defects in symmetry may be observed. There are some practitioners who have developed their mechanical powers to such an extent, and have become so absorbed in some mechanical specialties, so-called, that they are unable when they look at the human mouth to see anything but a possible bridge, crown, or plate; others have a clear vision as to dollars, their other sense perceptions being weakened from disuse. In fact, atrophy is often associated with hypertrophy, and the former may be an indirect result of the latter, both physically and mentally.

Specialties and specialists have done much to advance their particular lines of work, and this is greatly to be commended, but there are disadvantages as well, and these consist in the neglect of general considerations, which, if given some attention, would help much toward a more symmetrical condition.

In the enthusiasm and interest which is taken in certain lines of work in our profession, many of us forget that there are other departments of our work which should also receive attention; that, in many directions, our mental and bodily capacity is weakening through loss of function; that we are better dentists by being better citizens; that we are the best stomatologists when we have cultivated our hearts, minds and bodies in all possible directions around the one central object which draws us all together with a common interest and a common purpose.

THE EVOLUTION OF STANDARDS IN DENTAL EDUCATION.*

CHARLES C. CHITTENDEN, D.D.S.
MADISON, WIS.

In a paper read before this Section one year ago I reviewed the various steps by which dental educational standards had been slowly and laboriously advanced from a mere shadowy pretense of individual schools to the establishment by the National Association of Dental Faculties of a minimum educational requirement for admission to all schools, which was equivalent to two full years of high school, and also the adoption of a full course of instructions for graduation of four years of seven months each.

The four years' course was proposed by resolution in that body in 1899. Action was laid over for one year, and at Milwaukee, in 1900, the faculties' association deliberately and after careful consideration decided on its adoption, setting forward the time for its inauguration to the autumn of 1903, thus reserving three years more in which it would be possible to change their decision in case it should develop that the time was not ripe for such advance. Thus at the annual meeting of 1903 held at Asheville, N. C., the subject came up for final irretrievable action, which was precipitated by Harvard University Dental Department.

---

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee.

That school informed the association that it would "not at present extend its course to four years," assigning as its reason that it was engaged in contemplating the raising of its educational requirements for entrance at some time in the future.

A special committee had the matter under advisement for three days as to whether the association should "concede that Harvard is entitled to one year less time than other schools having an equal standard of admission, with the exception, it may be, of analytical chemistry and physics." The committee reported recommending that Harvard could not be granted such concession, and after a free discussion the report was unanimously adopted on a roll call of colleges. Harvard then resigned its association membership, and the resignation was promptly accepted. In all this the National Association of Dental Faculties deliberately, unanimously and finally placed itself on record as standing firmly for the four years' course.

Simultaneously at Asheville an attempt was made in the National Association of Dental Examiners to have rescinded the following standing resolution, adopted at Milwaukee in 1900 as a treaty of peace and good faith between the colleges and the examiners, viz.:

> *Resolved,* That no college not an acceptable member of the National Association of Dental Faculties be placed on or continued on the recommended list of this association.

This attempt to rescind failed, and the two associations adjourned in full accord and with the mutual conviction that the four years' course was established for all time, and that the two associations would stand firmly together for its maintenance as a criterion of the reputability of dental colleges.

Thus it transpired that every dental college in the faculties' association, and, in fact, every dental college in the United States save one, opened up the school year of 1903-4 with the four years' course inaugurated and advertised to the world as the established standard deemed necessary by the educators themselves for the proper preparation of the dental student for graduation and practice. It was a brave move—a grand achievement—and the profession at large gave a great sigh of satisfaction that the schools had made this advance step toward removing the stigma which had been cast in foreign countries on the educational methods and standards of the schools of the United States.

It seemed that there remained only the necessity to secure the further requirement of high-school graduation for matriculation (which step had been practically promised by most of our universities and actually inaugurated in some of them) to place this country in the forefront of the nations, with practically no peer. The dream of raising up a generation of educated, scientific professional gentlemen to serve as the standard bearers of dentistry for the near future seemed about to be realized.

The school year for 1903-4 opened with the new order of things, but to the great disappointment of many deans, whose freshman classes were much smaller than the year previous. This condition was largely accounted for by the fact that prospective students had hastened to take advantage of a last chance to graduate in a three years' course and had flocked to the schools the year before in large numbers. This fact also made the first four years' freshman classes seem abnormally small. Of course, the income to the schools was correspondingly small. To the older established and the endowed schools and departments of universities, this did not so much matter, as the check was, of course, only temporary. But the smaller proprietary schools at once took alarm at the decrease in income, and without regard, it would seem, to what effect such a course would have on their standing and reputability in the eyes of the public, began, within a month after the opening of the school year, to devise some plan for inducing the National Association of Dental Faculties to return to the old course of three years for graduation. An effort (which finally proved successful) was made to hold an extra meeting of the association at Buffalo during the Christmas holidays to act on such a proposition. At this meeting it was held and ruled by the president that no action could be taken or business transacted until the next regular annual meeting, but much time was spent in discussing the situation. Sentiment was divided about as follows: One faction, consisting of about one-third of the association membership and representing almost exclusively the proprietary schools struggling for existence, were avowedly for an unequivocal return to the three years' course of seven, or even six, months each. Another smaller faction favored a high-school diploma for matriculation and a three years' course of nine months for graduation. And, lastly, those schools having adequate financial foundation on which to bank in conducting their work on any reasonably advanced standards, those schools representing about one-half the membership in the association, stood and plead for professional honor and professional unity—stood firmly for no retrograde of standards and requirements. When the meeting adjourned it seemed reasonable to believe that no further attempt at lowering standards would be made.

When the national body adjourned at Asheville in 1903 it was with the general understanding that the next annual session would be held at St. Louis at about the same time in August, 1904, as would be held the International Dental Congress—that is, the latter part of that month.

It has been the rule of the schools to issue their annual announcements for the coming school year course some time in June, as the business for the coming year begins immediately after the old term closes. Had the National Association of Dental Faculties held to the plan laid out at Asheville as to the time of the annual meeting, these announcements would all have been issued on the basis of a four years' course before the meeting could occur, and a change in the course would have been practically impossible; but for reasons best known to themselves the majority of members have recently decided to hold the meeting in the City of Washington, June 9. Such a change in program is so unusual that it is but natural to seek a reasonable explanation. At this early date the annual announcements will not have been issued, and it would be entirely reasonable to infer that another attempt may be made to lower standards. Should such an attempt prove successful, there are a great many things likely to happen. It is not conceivable that the endowed and independent schools will tamely submit (even should they be in the minority) to a retrograde educational movement. They could in no sense afford it, nor would it be in accord with any of their traditions. They have for years submitted to being held back by the inability of the weaker schools to move forward rapidly on account of their financial handicap. It is but reasonable to expect that the faculties' association would either go to pieces or become divided into two separate organizations with separate standards.

The question at once presents: What would be the attitude of the legally-appointed examiners in the states which hold their boards responsible as to the judging of the reputability and standings of the colleges from which their applicants for license have graduated?

What would be the attitude of the profession at large? Will the men who are out in the open, bearing the heat and burden of the day before the public, tamely submit to the open discredit that would be cast on their chosen calling by a national lowering of its educational standards?

It seems impossible that such a calamity as a division of college forces on this question could occur, and still more impossible that a decided retrograde movement can possibly receive the sanction of a majority of the schools. But should this happen, it is safe to predict that the rank and file of dentists will put their stamp of disapproval on such a transaction in no uncertain manner. The prediction is reasonable that schools of the trimming and retrograde type would be allowed to fall back out of sight and be forgotten in the onward march of the development and evolution of dental educational standards.

SOME PHASES OF DENTAL EDUCATION.*

A. E. BALDWIN, M.D., D.D.S., LL.B.

CHICAGO.

In order to realize that we are living at a very rapid rate, we have but to look backward to see the progress that has been made in almost all lines within the memory of even the younger men of the profession. By observation we are shown that the education required to enable one to call oneself an educated artisan, scientist or professional person was very meager as compared with the demands and the requirements of to-day.

The question often arises in my mind whether or not stomatology, as a specialty, has kept pace with the march of progress in other lines, and especially in coincident professional lines. Much has been written, much is being written, and much more is being thought, as to the proper lines of progressional development in education in our specialty. Within the past few years we have seen that the National Association of Dental Faculties has, after long discussions, extended the requirements, preliminary and graduating, until now the time required in our most progressive schools is nothing less than a four years' course, with more strict preliminary requirements. However, by noticing the actions of some of our educators, we fear that there is a movement on foot—especially in the schools which are conducted by private ownership—because of a fear that with these added requirements the collegiate expenses will be increased, with a corresponding decrease in receipts; consequently these schools—which are conducted, if you please, for financial gains incidentally—look on the matter as a strictly mercantile transaction, and I fear that there may be a retrogressive move lessening the preliminary requirements, and also lessening the amount of time necessary to be spent in schools in order to graduate.

It has been my observation for a score of years that there are many people practicing with us who seem to have a fear of acquiring too broad and comprehensive an education; indeed, a short time ago a paper was read before the Odontological Society of Chicago by Dr. H. T. Carlton, San Francisco, in which he advocated a radical advance in not only the preliminary requirements for entering our colleges, but also an emphatic advance in the requirements which must be met before graduation is allowed. This paper was read before the largest assemblage of dentists ever gathered in the world, and, much to my surprise, many men who had been classed with those who were in favor of advanced education showed by their discussion of this paper that apparently they were afraid that the young men entering our field might be too broadly educated and too well grounded in knowledge, not only of the whole human frame, but in all other scientific directions. It was convincing to a reasoning and observing mind that the only hope for rapid and thorough educational progress in our field lies in the schools which are maintained and conducted otherwise than for financial ends. In other words, the hope of dentistry, in its progressive advance, lies more largely than we will admit, first, in the schools which are founded and conducted in connection with our great colleges and universities, and, second, in the gradual elimination of the schools which are conducted by organized capital for the income which it produces, or by the organized professional band who, for notoriety or gain, organize and conduct schools which apparently are more anxious for numbers than for intellectual prominence. This is said with regret and with no intention to belittle or attack any school or college in particular, but with recognition of the fact that if the teachers or the organization have a direct financial interest in the income, gross and net, it must hamper or modify the influence which the school and teachers may exert over the student and the requirements demanded of him.

A great movement in advance can be forced if our national organization of the several state boards unify and exact constantly advancing requirements for entering our chosen field.

DENTAL EDUCATION.

A RETROSPECTIVE AND PROSPECTIVE VIEW.*

JOHN S. MARSHALL, M.S., M.D.

SAN FRANCISCO.

"We will not anticipate the past, our retrospection will be all of the future."

It is my purpose in this short paper to take a hasty retrospective glance at the history of dental education in the United State, that I may hold before you for a moment a picture of progress that has seldom been equaled in the history of educational advancement, and then to change the view and hold before you another picture, a prospective view, the realization of which will be no more difficult to us and our children than was that of the first picture to our fathers and ourselves.

"Past and to come seems best; things present worse."

Shakespeare never wrote a truer line than this, for, if we were satisfied with the present, there would be no progress in the future. Satisfaction with the present brought decay and ruin on the ancient Egyptians and on the Roman Empire.

---

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee.

A RETROSPECTIVE VIEW.

We learn from history that the art and science of surgery is an outgrowth or evolution of the tonsorial art. Two hundred years ago the barber was also the surgeon. His functions were to shave and cut hair; to bleed the prince or the pauper; to bind up wounds and set broken bones. The striped red, white and blue pole which stood before his shop indicated that he was ready on occasion to bleed his patron, bind up his wounds or set his broken bones. The term applied to him was barber-surgeon. His social position was that of a barber, a person to be petted on occasion, or insulted or kicked at the caprice of those of higher social position. To-day his learning and skill have placed him on the highest pinnacle of fame by reason of which kings and emperors have made him their confidant, and freely and without fear have placed their lives in his keeping.

Dental surgery was likewise evolved from the art of the barber, the tinker and the village blacksmith. A little over sixty years ago there was no such institution as a dental college, no such organization as a dental society or even a journal devoted to the interests of dental surgery. At that time the only means of education in dentistry was by the old system of apprenticeship. The dentist in those days had no social or professional standing; he was envied by the barber and looked down on by the doctor of medicine. To-day he is regarded as a member of a noble profession, standing shoulder to shoulder with the physicians and surgeons and dividing with them the honor of adding to the comfort and longevity of the human race by reason of their learning and technical skill.

The evolution of the surgeon, from the barber to the scientist, required several centuries, while the evolution of the dentist from his low degree to his present honorable position has been accomplished in as many decades. This has been wrought partly by the energy and forethought of the pioneers in the profession, but principally by the more favorable environment which surrounded the infant profession.

In these days of the rapid spread of knowledge and learning, the development of the arts and sciences and of the inventive faculties, the ignorance, prejudice and bigotry of the race have been swept away and all men and all movements, either social, political or scientific, are given an opportunity to develop, each standing or falling according to its merit. Surgery in its early struggles had to fight against the ignorance of the people, the prejudice of the scholars and the bigotry of the church, and little progress was made until the beginning of the last century. The discovery of the microscope, of vaccination, anesthesia and antiseptics made it possible for medicine, surgery and dentistry to reach their present high development, a development which is still progressing and must continue to advance in the future.

Dental education may be said to have had its beginning in the organization of the first dental college. This institution, as we all know, was incorporated and established in the city of Baltimore, Maryland, in the year 1840. Its entrance requirements were simply a desire to learn. Its curriculum was anatomy, physiology, chemistry, development of the teeth, principles of operative and mechanical dentistry and laboratory instruction; yet with this meager course of instruction, it developed some of the brightest minds that have been found in the ranks of the profession. Its requirements for graduation were for practitioners of five years' standing, one course of lectures of about four months; for students, two courses.

A reference to the text-books of this period will show how circumscribed and narrow was the field of study, when compared with the text-books of to-day and the requirements for entrance and graduation from our best dental colleges.

With the organization of other dental colleges in various parts of the country, a rivalry sprang up between them, and as the profession advanced in scientific knowledge the curriculum was broadened and the courses extended to five months in each year.

For many years thereafter little or no advancement was made either in the course of instruction or the length of the college year. Hydra-headed commercialism had entered into the schools, taken them by the throat and well-nigh strangled them, for the great aim in most of them had become large classes and a substantial dividend at the end of the year to be divided among the incorporators.

The organization of dental societies, local, state and national, and the establishment of dental journals, which followed very soon after the incorporation of the Baltimore Dental College, and through the succeeding twenty years, were the most potent elements in arousing the colleges from the stagnation into which they had fallen through the commercial spirit. The might and power of these influences are still exerted for the uplifting and stimulating of the best impulses in education, professionalism and ethics. To the dental societies and the dental journals the colleges and the profession at large owe much of their success and scientific advancement.

The regulation of the practice of dentistry by the passage of laws for this purpose, by several of the older states, was an advance step of great moment to the interests of higher dental education. These laws recognized dental surgery as a department of medicine, and for the first time in history it was raised to the dignity of a professional calling. The public had heretofore looked on the dentist as a mechanic, spoke of the trade of dentistry, referred to his office as his shop and his operations as jobs. And, although the dental surgeon was the professor of the honorable degree of D.D.S., conferred *en course,* many persons addressed him by his title in the same spirit that they spoke of the barber as "professor," or the chiropodist as "doctor."

Time, however, changed all this, and the public, by degrees, came to look on dentistry as a professional calling worthy of the best minds and greatest talents. As a result of this change of status in the minds of the public, the dental colleges of this period were overcrowded with students. The demand for more schools seemed imperative, and, as a natural result, many were organized, too many for the best interests of education. Competition of a commercial character, even more strenuous and active than before, took possession of many of the colleges, and some of the weaker schools, feeling that they were being crowded to the wall, opened their doors to any who could pay the fees, promising to graduate them at the end of two courses of lectures. In many instances students were graduated after one course of lectures, and, to our shame be it said, diplomas were issued in some instances to men who had only attended a sufficient number of lectures to identify themselves with the graduating class.

The courses of instruction in the dental colleges of this period were so diverse in subjects and study requirements that students had great difficulty in passing from one college to another, as the faculties of the different colleges often refused to give credit for work done in other institutions. This state of affairs became so unsatisfactory to the colleges and students that several of the leading schools issued a call for a conference of all the dental colleges, for the purposes of harmonizing the courses of study and arranging for comity between the schools and such other matters as should be of mutual benefit to all concerned. This conference resulted in the organization of the National Association of Dental Faculties.

The organization of this association marked a great epoch in the history of dental education, for through its deliberations and established rules, it has exerted a tremendous moral influence over the colleges, both within and without the association. It has kept the colleges within the association up to its prescribed standards for the admission and graduation of students, while those on the outside have been compelled by the state examining boards to seek admission to the association and place themselves in harmony with the requirements of its educational standards. It has brought order out of chaos, in dental teaching; it has harmonized the courses of instruction and has stopped the practice of granting degrees *in absentia*. It has made it possible for students with proper credentials to finish their course of instruction in any college that they may elect. It advanced the requirements for graduation from two to three years. It established an educational entrance requirement and gradually raised this requirement from nothing to a certificate of having passed the examinations of the second year in high school. It has introduced technic teaching in operative and prosthetic dentistry. It has improved and extended the curriculum from time to time by adding such important subjects as physics, embryology, general materia medica and therapeutics, general pathology, bacteriology, comparative dental anatomy, orthodontia, general and oral surgery.

Up to one year ago the minimum preliminary requirements for entrance to our dental colleges was a certificate of having passed the studies of the second year in high school, and for graduation, three full courses of instruction of from seven to nine months in each year.

Until three years ago this was the same standard as that required by the medical colleges. At this time the medical courses were extended to four years and the minimum entrance requirement was advanced to a diploma from a four-year high school. A few of the better class of medical schools now require that the student shall have passed the studies of the sophomore year in liberal arts or natural science, while one insists on the bachelor's degree.

At the present time the minimum preliminary requirements for entrance to the dental colleges, having membership in the National Association of Dental College Faculties, is a certificate admitting the student to the third year of a high school or its equivalent, while that for graduation is four annual courses of instruction of not less than seven months in each year. This, it seems to me, is a record of which the dental profession need not feel ashamed, and yet it should not felicitate itself too much over its progress, for much greater advancement might have been made in educational matters if the colleges could have been united in their work from the beginning.

A PROSPECTIVE VIEW.

The second picture, or the prospective view, must necessarily be one made up largely of personal opinions and impressions, but nevertheless opinions and impressions bred of many years of experience and general observation.

The great need of the profession to-day and for the future is, in my opinion, higher preliminary education and broader and fuller instruction in those fundamental sciences which make up the sum total of a dental education. The profession has done well in the past, but it can not afford to relax its efforts or to take a backward step, now or ever.

For many years the minimum preliminary educational requirements for entrance to the dental colleges were the same as for matriculation in the medical schools, but at the present time they have fallen somewhat behind. This, in my judgment, is a mistake, and it should be rectified at the earliest opportunity.

The requirements for matriculation and graduation in dental surgery should be in no way inferior to the requirements of the medical schools. The courses of instruction in the fundamental sciences should be the same, and during this period the medical and dental students in the great universities should be taught together, and no distinction made between them. By this plan better and more thorough work can be done and at much less expense. This saving of expense would make it possible to employ teachers at an adequate salary who would give their whole time and attention to teaching and original investigation, and as a consequence the teaching would be of a higher grade and the work of the student would be more enthusiastically performed.

What we need to-day and in the future is wide-awake teachers for the fundamental sciences, teachers who are full of their subject and who can impart knowledge in such a fashion that the student can not help being interested in these, to him, otherwise dry subjects. If the teachers of anatomy, physiology, chemistry, etc., are not enthusiastic in their work, the student soon loses interest in them, and turns to the more practical subjects to which he often gives time that could be spent to better advantage on the fundamentals, as he finds, to his chagrin, in after years.

In my work as an examiner for the Dental Corps of the U. S. Army, I have found that the majority of the candidates who have presented themselves for these examinations were deficient in preliminary education and in those subjects usually denominated as the fundamental sciences. In the practical departments they were as a rule quite well prepared. The best marks were usually obtained in operative and prosthetic dentistry, crown and bridge work and orthodontia. In fact, many of them were good jewelers, but lacking in that knowledge which marks the truly professional dentist. This is not the fault of the curriculum, for with the subjects that now comprise the courses of study in our better dental colleges the conscientious, hard working, well prepared student will receive an excellent professional education.

The most serious difficulties which the teachers of the fundamental sciences experience in their work is the lack of time properly to cover the subjects and mental deficiency on the part of a large number of students in every class, whose minds have not been sufficiently trained and disciplined by previous study readily to grasp or comprehend the sciences which they are endeavoring to teach. As a consequence, the instructor is obliged to suit his teaching to the comprehension and ability of these students, while those of higher educational acquirements, who could progress much more rapidly had they the opportunity, lose interest in the subject for want of a stimulus to study. This fault can only be corrected by insisting on a higher grade of preliminary educational requirements, and I most sincerely hope that the Faculties Association will not only raise these minimum requirements to graduation from a four years' high school or its equivalent, at its next session, but will recommend the completion of the sophomore year or a full academic training in the liberal arts or natural sciences, as the proper preparation for the study of dental surgery. It is possible at the present time for students of medicine to procure the bachelor's degree in natural science and the degree in medicine by combining the two years' work of the junior college with the four years' work of the medical school. The University of Chicago, the University of Michigan, the University of California and Cornell University now offer such courses, both degrees being conferred on the candidate after the completion of his full medical course.

This is a movement in the right direction and I can see no reason why the universities having dental colleges should not offer the same inducements to their students in dental surgery. With such a class of students the work of the instructor would be a joy, while the profession would gain very greatly by the addition to its ranks of a class of more highly educated practitioners.

A young man who has received a college training has usually been taught the principles of social and political ethics and is therefore better prepared to understand and appreciate professional ethics. Such a young man is generally imbued with higher standards of conduct and of living. He recognizes the ethical rights of others and demands that he be accorded the same rights. Such men are seldom guilty of conduct that brings reproach on their profession. They are seldom found in the ranks of the advertising quacks or those who selfishly patent a remedy, an instrument or an improvement in methods, which would be of benefit to suffering humanity, forgetting, or not caring, that nearly every remedy they employ for the cure of disease, every instrument they use, or operation they have been taught to perform, was thought out and perfected by some member of the profession who preceded them, and who freely and unselfishly gave these to their brethren for the benefit of suffering humanity. The profession needs more of this unselfish, better educated, truly professional class of men. It needs to stamp out the commercial idea and install in its place the true professional spirit which places our duty to our patients and the state first, leaving the question of the fee for future consideration.

The lengthening of the college course from three to four years will call out many differences of opinion as to how the extra year shall be employed. Those who teach the practical branches will want to extend instruction in operative and prosthetic technics, while those who teach the fundamental sciences will ask for more time and more thorough courses. The latter, to my mind, is at present the most important side of the question, and it should be given careful and conscientious consideration, for the future of the profession depends on how it is decided.

To obtain the highest degree of instruction the teacher must be a specialist in his department, and with the financial inducements that can be offered by the average dental college such teachers for the fundamental sciences are difficult to obtain.

Specialists in the practical subjects of dental surgery are plentiful and, as a consequence, this part of the training of students leads the theoretical and the scientific.

The student is naturally attracted to those subjects on which he thinks he can see that his future financial success as a practitioner depends. He is, therefore, inclined, through mental shortsightedness and inexperience in the profession, and from his inability to comprehend its responsibilities and his duties to his patients and the state, to neglect those subjects which are of the greatest importance in the development of scientific dentistry, and hence to the welfare of his patients and the best interests of the state. He therefore devotes his energies to those departments which appear to him to promise the largest and most speedy returns in money for the time and study spent on them.

We are a nation of buyers and sellers. Commercialism dominates our people. Trade and trade interests rule the nation. How, then, can we find fault with the student if he partakes of this spirit of commercialism that he can see everywhere around him, that he reads in the newspapers, hears talked on the streets and in the parlor; sees in the bitter competition of some professional men, and can not help but know exists in the management of many institutions of professional learning?

The best interests of higher dental education demands that the management of these schools should be taken out of the hands of the individual or the teaching faculties and placed under the control of the state, or of the trustees of our great universities, for the reason that the majority of the dental schools to-day are still per force commercial institutions, dependent on the fees of students and the profits of the infirmaries to maintain them and pay the teachers and demonstrators. Just as long as commercialism exists in our system of dental education the best results can not be obtained. The interests of the students should be paramount, but this interest is often obscured by holding the dollar too close to the eye. It is marvelous how small an object will obscure our vision if we but hold it close enough.

The first dental college was organized on the commercial basis, and I do not know of a single dental school, even those under state control, that are entirely free from some form of commercialism, for in all of them the fees of the students, or the receipts of the clinics, bear a more or less important relation, either to the salaries of some of the professors or demonstrators, to the buildings they occupy or to the apparatus or furnishings.

In most of the state institutions the appropriations are too small properly to conduct the schools, while in the colleges connected with the large endowed universities no endowments have been made to the dental schools. They are thus left in a measure "to work out their own salvation," in many cases "with fear and trembling," as I know from personal experience.

We could wish that the legislators of the states having professional schools in their universities would appropriate for their support with a more liberal hand; and that good people with fortunes they can not spend and do not know where to bequeath, would endow the dental colleges and place them above the degrading necessity of catering to the commercial spirit, and entering students who have not a proper educational qualification to begin the study of dental surgery, or who are deficient in that peculiar aptitude for a professional life, through which alone they can hope to develop practitioners who will be an honor to the institutions that are responsible for their education.

I have confidence to believe the day is not far distant when all of the dental schools will either be liberally provided for by the state or abundantly endowed through the munificence of a Rockefeller or a Carnegie. The American people are liberal and just toward all educational efforts, and whenever they are convinced that the best interests of the citizen and the state demand that they render financial assistance to any individual enterprise, it is usually forthcoming.

Another serious drawback in our system of education is the failure to provide advanced standing in the dental course for students who have taken the bachelor's degree in liberal arts and sciences.

These students have had a sufficient amount of didactic teaching and practical laboratory instruction in chemistry, botany, morphology, physiology, zoology and comparative anatomy, etc., to more than equal the work of the freshman class in the dental schools, and under these circumstances their higher preliminary qualifications should be recognized by advancing them to the sophomore class of the dental course. By adopting a policy of this character ambitious students would be encouraged to complete their academic training before entering on the study of dental surgery.

As the matter now stands, the college graduate is placed on the same footing as the student whose qualifications are only those of a second year course of a high school, and the extra six years of study pursued by him in the languages, mathematics, literature, history and the science, count for nothing. This is placing a premium, I was about to say, on ignorance, but I will modify the statement and say, on the minimum requirements for matriculation, and thereby turns away many young men from the doors of the dental schools who would have been an honor to the profession.

I am constrained, also, from my sense of justice, to make another suggestion, namely, on the matter of advanced standing for medical graduates. Since the adoption of the four-year course for medical and dental colleges there would seem to be no good reason why medical graduates who have taken a full four years' course should not be advanced to the junior grade of the dental colleges.

The four years of training of the medical graduate, preceded by a full four years' high school course as a minimum matriculation requirement, is certainly equal to the freshman and sophomore courses of study in the fundamental sciences as taught in the dental schools, preceded by only two years of the high school course as a minimum entrance qualification. It would therefore seem no more than a just recognition of the scientific work performed that he should receive such advanced standing in a dental course. If such students, devoting their full time and energy to the study of the purely dental subjects for two years can not make as good operators as their fellows who entered with the minimum qualifications and have spent four years upon the dental course, then the value of higher education as a prerequisite for professional study is a myth and a snare.

Let us look at this matter in a reasonable light and place ourselves on record as favoring the proposition of giving due credit for scientific work performed by candidates for matriculation who hold the B.A., B.S. or M.D. degree from colleges and universities of recognized repute. Scientific knowledge is of as much value to the dental surgeon as it is to the physician and the surgeon, for without the employment of this knowledge in his profession, the dentist is nothing more than a handcraftsman.

DISCUSSION

ON PAPERS IN SYMPOSIUM ON DENTAL EDUCATION BY DRS. EAMES, CHITTENDEN, BALDWIN AND MARSHALL.

Dr. Eugene S. Talbot, Chicago—Anticipating that something might be said in the chairman's address in regard to the length of term in the dental colleges, and the position that would be taken at the meeting in Washington, I wrote letters to Professor Eliot of Harvard and to President Harper of the University of Chicago, asking them to prepare papers for this section. President Harper was unable to comply with my request, but I have a letter from Professor Eliot, which I will read at this time.

Dear Sir: I shall not be able to attend the meeting of the Section on Stomatology of the American Medical Association at Atlantic City, June 7-10, 1904. The proper person to state the position of Harvard in regard to the future policy of its Dental School is the dean of that school, Dr. Eugene H. Smith, 283 Dartmouth Street, Boston.

The policy of the Harvard School is not commercial in the least. It is steadily endeavoring to raise the standard of dental education, and has in a good degree succeeded. Just now it is trying to raise the standard of the admission examinations to the school, and is finding that a difficult task. It can not add, at the same time, to the length of its own course. Moreover, the school has been struggling for several years to maintain a close connection with the Harvard Medical School. The task has proved difficult because of the rapid improvement of the Medical School consequent on its admitting none but the persons who already hold a degree in Arts or Science. The Dental School must accomplish both the tasks to which it has set itself before it can lengthen its course to four years. The Section on Stomatology may rest assured that the Harvard Dental School will continue to do what it always has been doing—namely, contribute to the improvement of the preparatory course for the dental profession.

Very truly yours. Charles W. Eliot.

I am sorry to say that Dr. Smith can not be present, but Dr. Briggs will give us some idea of what the school will do.

Dr. E. C. Briggs, Harvard Medical School—I am sorry that Dr. Smith can not be here to give you the best idea, and as it was only a few days ago that he told me he could not be present, I have not been able to make any real preparation or collect any special data. I can, however, point out one or two things and state a few facts which I hope will impress on your minds the idea that Harvard is not blocking in any way dental education. In fact, it seems ludicrous that others should have placed her in such a position, when she has always been struggling quite the other way, and, I may say, struggling against her own commercial interests. We have decimated our classes time and again by the advances we have made over other schools.

The question is, What elevates the profession? We speak about the progress we have made, but we lose sight of what really elevates the profession as a whole. There are plenty of men in the profession to-day who have elevated themselves as high as any one could wish, who have not had any particular preliminary training. They have had the genius and have made the geniuses, but that does not raise the profession as a whole. That is the feeling that we have at Harvard. To set the profession right before the world, attention must be given to the character of the men and their scholarly attainments, and that is the reason we have paid so much more attention to preliminary requirements than we have to the length of the course. The length of the course is a little misleading. It is four years of seven months; Harvard already has three years of nine months. We are only one month short. With that, and with our entrance requirements, we do not feel that we could wipe out our school altogether. We have about cut it in half now, and what better evidence can you have that we are not commercial? If we were commercial we would take in some of the men who come from other colleges who write to know what their position will be on coming into our school. Not one has accepted, because we say, we will give you time allowance, but you must pass every examination before you can graduate. That is not what they want, and they do not come. For the post-graduate our terms would be entirely different. That does away with the suggestion that our line of thought is due to any commercialism. I wish that you would send, as we have done, for purposes of comparison, to the different colleges, and see what their examination papers are and compare them with ours. Not one man out of ten with a high-school education can come into our school. He must pass the examination with ability to go into college—not twenty-four points, but as many points as he goes. He has got to pass just as good an examination as if to enter Harvard or Yale—I speak of them because they are nearer. So it seems to me that Harvard has been put in an unfortunate light, diametrically opposite to what she really is at heart. The time that a man is in a professional school is of great value to him; we appreciate that as much as anybody else—I do not believe ten years would be too much, if you wish to reach the highest ambition of life. The idea is, that having provided a certain amount of good training, which we think we do in three years, the next best step is to have the man who comes into the school one who is already a scholar and fitted to take up any of the liberal professions. You and I are helped just as much by that uplift. We can not stand back and say we did pretty well and that we only had "reading, writing and arithmetic." If the standard is raised by making it necessary to have something more than that, you will get professional standing. The profession will not make its highest success until the men who come into it are men of education and scholarly attainments.

Dr. Williams, Boston—One of the things which I thought I would object to in teaching in Harvard was that I would have to teach with men who were not prepared to learn. I am glad to know that the standard of the examination has been advanced so that the students are better able to learn. The preliminary preparation is necessary in order to know how to learn to the best advantage.

Dr. Truman, Philadelphia—I feel in a somewhat embarrassing position, coming down here as if we were going to attack Harvard. That is not my purpose. So far as I am concerned, I want to advance dental education along the best lines possible. In 1884 we organized the Association of Faculties, and for twenty years we have worked steadily to bring up the standard of education to four years. At Asheville last year, when we supposed we had established that, without any prospect of its being changed, we received a blow from the very highest educational center in this country—Harvard. They requested that they should be given the privilege of three years, because they intended to advance the preliminary standard to the A.B. degree eventually, and for that reason and for the higher standard which they claim at present, they believe that they had a right to a three years' course. I was chairman of the committee which took that matter in charge, and we could not, under the circumstances, agree to the proposition, because other universities in this country had practically the same standard and the same length of time. Now the action of Harvard on that occasion was an encouragement to the commercial schools. I know very well that Harvard has never been a commercial school. No one can charge Harvard with that. It has always been exactly the contrary, and that is why I was astounded at that time at the action of Harvard. After they left the Association of Faculties we heard that we were to be met, first at Buffalo and in a day or two at Washington, with the commercial idea of going back to three years because the schools can not maintain themselves. Now, Harvard may not have meant this. Harvard did not mean it, but at the same time that influence has been an injury to general dental education in this country, and I don't see how Harvard can explain it.

We have had this afternoon a good deal that is of value in these papers, and as a rule I am in unity with them, especially with the paper of our chairman. I agree with the proposition that the higher in a general way you can educate a man the better, but you must have that education properly arranged in order to be of value. The idea to me is pre-eminently absurd to suppose that because a man has an A.B. degree that he is qualified thereby to become a dentist. It is a fallacy. The high-school degree is equally fallacious. What we need in dentistry is an education that will fit a man to become a dentist. If he is to be a dentist he should come up from the mechanical school, through the higher schools, and then reach a point where he can be of value to himself and the community at large. There is probably not a man here in this room who ever had more than two years of four or five months' study in the professional schools. I do not believe that we can make dentists out of all men, whether they have the A.B. degree (and we have a number of them) or whether they have the high-school degree; that is not the point. We must go deeper if we are going to have symmetry in our educational effort. My own idea has been that the poor dentists we have turned out have, as a rule, been men of higher education—not the fault of the higher education, but the fault of a lack of proper symmetry in that education. Let me illustrate: I had two boys to educate. One was my own son, the other a nephew. My own son I insisted should take a six years' course to acquire a proper classical education. He graduated with the highest honors of the university and with nothing in anything else. The other boy was mechanical. I insisted on his going through the manual training and from the manual training school to the university, and from the university to a post-graduate department in one of our large manufacturing establishments, making nearly eight years in his particular direction, and at the present time, at thirty years of age, he is superintendent of motive power in one of our largest establishments in Philadelphia. My own son became a teacher. That is what I mean by symmetry in education; training the men from the very beginning so that they can practice whatever they expect to be their calling, and not supposing that because a man has an A.B. degree or any other degree of that character, that he can go into a dental school and become a dentist. The thing is an impossibility and a fallacy. This very day I have before me large numbers in our own university who are utterly unfit to practice dentistry, and it is a source of tribulation to me that I have to meet that sort of thing. They have not been properly trained from the beginning. They have not the manipulative ability that ought to come with good practice, and they will never get it, because they have reached an age when it is impossible that that shall be perfected in the individual. If we are going to advance education we must look at it intelligently. Let us come down to practical matters. Let us take our own experience, the experience with me that covers nearly half a century, and we know it can not be done in this way. Harvard will not do it, because in the first year Harvard ignores almost entirely the technic of dental education. In the old laws regulating mechanical work in my own state, young men had to go into apprenticeship, working for four or five years until they reached their majority at 21, before they could practice any of the mechanical trades. Then they were skilled in their work. Here we are trying to turn out men in three years in one of the most complex mechanical professions that I know anything about in this world, that of dentistry. We would turn them out with a fundamental knowledge of anatomy, bacteriology, histology, etc., and the mechanical training almost entirely ignored. Is that what we are here for? Are we here for that purpose alone? If we are, then I am not a dentist.

Dr. Williams, Boston—Dr. Truman is right in his views regarding the manipulative qualifications of a dentist. It is necessary that they should be trained properly and early. I have known some of the best manipulators to be the greatest failures in their operations from not knowing when and how to exercise their manipulative skill. I have known of one or two instances of fatal result, from very high skill misplaced.

(This discussion is to be continued. As the issue of June 25 is the index number, it will be continued in the issue of July 2.)

Medical Study Trip to the German Spas.—The fourth German study trip for physicians will include this year the watering places of Johannisbad, Salzbrünn and six other resorts. The party will assemble at Görlitz September 7 and disband at Breslau eleven days later. The total expense for the trip will be about $34. The sanatoria and convalescent homes at Görbersdorf and other points on the route will be visited and also the model miners' quarters at Waldenburg. Further particulars may be learned on application to Dr. W. H. Gilbert, Baden Baden.

NOTES ON CURETTAGE.

WITH REPORT OF A CASE OF ACCIDENTAL PERFORATION OF THE UTERUS.*

A. P. STONER, M.D.
DES MOINES, IOWA.

At one time the curette was offered as a panacea for nearly every uterine disorder. Indeed, it was often ruthlessly used on the most insignificant provocation, where Nature, with the assistance of a little general treatment, would have sufficed to cure. Retained secundines following abortion and miscarriage may usually be readily removed with the finger. It is not advisable, however, to immediately dilate the uterus in order that the finger may be employed, for in cases in which the organ has become contracted to such an extent that instrumental dilatation becomes necessary, the amount of débris is found to be small, and may readily be removed with the curette. On the other hand, when there is an abundance of foreign tissue in the uterus, its removal with the curette is attended with much difficulty, and one is never sure when the cavity has been emptied.

I recall one instance of an incomplete abortion in which, after having apparently emptied the uterus with the curette, I was about to insert the packing (which was then the practice), when I found that my finger could be readily introduced, and was much chagrined to find that the organ still contained a considerable amount of detritus.

I have long since ceased the practice of packing the uterus after this operation. Except when necessary to control hemorrhage, I see no reason for such procedure. Gauze acts as a dam instead of a drain, and by obstructing the free outflow of disorganized tissue and toxins, serious results have followed its use. Gonorrheal endometritis should never be treated with the curette. The most painstaking operator is seldom, if ever, able to remove all the infected endometrium with the curette. I had occasion once to remove the organ immediately after having thoroughly curetted it, and was surprised to find many islands of tissue which had entirely escaped the curette. Even if it were possible to remove all the infected endometrium and thereby destroy the main army of the invaders, a large reserve force may still remain within the fallopian tubes and later attack with renewed energy the new-formed cells of the uterine cavity. Once the fundic cavity becomes infected with the gonococcus, the tubes rarely, if ever, escape its ravages. If, therefore, the tubes are already infected, the use of the curette will only create greater perturbation in the infected area, and, indeed, may be the means of spreading the infection.

Curettage has become such a common practice that there are few practitioners who will not attempt the operation. My observation leads me to believe, however, that comparatively few surgeons become skilled in the use of the curette. Faulty technic is often manifested in operations on cases of simple endometritis. Then, again, cases for curettage are not always properly selected, in either of which case the patient receives little or no benefit; indeed, may become much worse. The uterus should be first outlined bimanually, and before the curetting is begun, the uterine cavity should be carefully explored with a dull wire curette. Then with the image of the uterus, and especially its cavity in mind, every part of its surface is systematically scraped with a thin sharp curette, the cornua being separately treated with the smallest sized instrument. The cavity is then washed with sterile water, and no packing used except in septic cases; a little loose iodoform gauze may be left in the vagina, which should be changed twice daily.

Practically the only danger arising from the operation is that of infection. This can usually be avoided by the practice of scrupulous cleanliness. Indeed, the preparations for curettage should equal those for vaginal section. Infection following perforation of the uterus by the curette appears to be a rare occurrence. The peritoneum is able to take care of a great deal of toxic material, so long as it remains unimpaired, such as may be produced by handling or prolonged contact with the atmosphere.

An accident occurred in my practice recently, it being the first one of the kind in an experience of more than fourteen years, during which time a fairly large number of such operations have been done. The case is briefly as follows:

Mrs. V., aged 37, very corpulent, 5 children, no miscarriages. Six weeks previous to operation she was confined at full term. The child had been born some 20 minutes when I arrived, and the placenta was still *in situ*, and an alarming hemorrhage was going on. I quickly applied the usual methods for delivery of the afterbirth and on failing, introduced my hand into the uterus and found a portion of the placenta, covering a surface half the area of my palm, still adherent to the uterine wall. Its detachment was very painful to the patient, and in spite of my somewhat prolonged effort to remove it, some placental tissue was left attached to the surface of the uterus, it being completely adherent. Although my hand had been hurriedly sterilized, I was somewhat surprised that no immediate infection ensued.

The patient was up at the end of 10 days and began to look after her household affairs. The lochia continued for 3 or 4 weeks, and was succeeded by a sanious fetid discharge. Pelvic pains soon appeared and were followed by considerable general disturbances, such as headache, malaise, accelerated pulse, etc., and I decided to curette.

The operation was done under chloroform at the patient's home. Owing to the thickness of the abdominal walls the uterus could not be outlined. No dilatation was necessary. A medium-sized dull curette was introduced in order to outline the uterine cavity and ascertain if any loose débris was present. Scarcely had the maneuvering begun, when the instrument suddenly glided into the abdominal cavity. In order to satisfy myself that it had passed beyond the uterine cavity, I permitted it to pass in its full length, which by actual measurement proved to be 8.5 inches. The cavity of the uterus was found to be about 3.5 inches deep and contained but little débris. The endometrium, however, was thoroughly gone over with a large sharp curette and the operation completed without uterine irrigation or packing. Carbolized vaginal douches were given daily and the recovery was uneventful.

The patient is now, three weeks after the operation, fully convalescent and feels well.

Had the uterine infection been of a virulent type, this report, had one been made, would doubtless have shown a different result. The walls of the uterus at the site of the perforation must have been extremely thin and much softened, for no apparent resistance to the curette was offered, and I believe the accident might have occurred to one more skilled in the operation. The same accident once happened to Pozzi.[1] In his case bilious vomiting occurred on the day following the operation. The accident is a horrible possibility in any case, but only a bungler would meet with it except when the uterine walls were softened, as has frequently been found in cases of infection following labor and miscarriage.

Special Article.

THE PROPHYLAXIS AND TREATMENT OF FOURTH OF JULY TETANUS.

The annual epidemics of Fourth of July tetanus have shown only too plainly how ineffective are our best and most hopeful methods of treating lockjaw. While the figures for the fatality of traumatic tetanus generally quoted in text-books give 70 to 80 per cent. of deaths, yet we have every reason to believe that in the tetanus following blank cartridge wounds there are much fewer who recover. In investigating the cases of last year it seemed that not much, if any, more than 5 per cent. recovered, and this in spite of the use in many cases of antitoxin, as well as other recognized methods of treatment. This is probably in part due to the age of most of the victims, for the prognosis is much worse in children than in adults. It will be remembered by many of our readers that last year THE JOURNAL[1] investigated the results of the accidents of the celebration of the Fourth. The following is an extract from the tabulated statement there given:

Deaths from tetanus	406	
Deaths from other causes	60	
Total deaths		466
Non-fatal injuries	3,983	
Total persons dead or injured		4,449
Tetanus cases from blank cartridge	363	
Tetanus cases from all other known causes	29	
Other injuries from blank cartridges and firecrackers	2,461	
Other injuries from fireworks, powder, cannon and all other causes	1,364	

From this table it will be seen that the gravest danger of the Fourth is tetanus, which accounted for 406 out of 466 deaths, and that of these cases of tetanus those in which the cause was known showed that the infection occurred in a blank cartridge wound in 363, as against other wounds in 29. We were able to learn positively of but 7 recoveries in addition to the 406 deaths, so that the mortality would seem to be well above 95 per cent. For these reasons it seems advisable to present a thorough consideration of the matter of the prevention and treatment of Fourth of July lockjaw before the next epidemic comes.

THE PATHOLOGY OF TETANUS.

Because there are a number of features in tetanus quite different from those seen in more common diseases, it may be well to first consider the biology of the disease, since the treatment must necessarily be based on the nature of the processes that occur in its origin, evolution, and course. In the first place, the bacillus of tetanus is one of the few anaërobic organisms that are known to be pathogenic to man, and in this respect its range is quite limited. Occasionally the organisms become so modified that they can grow exposed to the air, but this is rare, and is practically not seen in human pathology. The conditions in which tetanus is usually seen depend on the anaërobic nature of the germ, and the famous "rusty nail wound" is dangerous not because of the rust, but because it passes into tissues far removed from air. For the same reasons mixed infections are favorable to the development of tetanus, for the other organisms requiring oxygen for their support use up that which may reach them and so make conditions favorable for the tetanus bacilli. Injections of small quantities of pure tetanus bacilli alone into a guinea-pig may not cause tetanus, when a much smaller quantity associated with the staphylococcus would do so. Furthermore, it has been abundantly shown that the virulence of these bacilli is much greater if they are sown in necrotic tissue or burned areas, which may depend on the fact that such areas are bloodless, and therefore poor in oxygen. These facts alone are sufficient to explain why certain wounds are more favorable than others for the onset of tetanus.

Another important characteristic of the organism is its habitat. In a city the size of Washington there will occur an average of about five cases a year. It is, therefore, evident that the germ can not pass directly from case to case, but must spend the greater part of its career either as a harmless saprophyte or else in some other host, only living on human tissues as a rare incident in its career. As tetanus is not frequent enough in any other animal to explain its continuance of existence as a parasite, we are compelled to fall back to the belief that it lives the greater part of its existence as a saprophyte. The organism can be found anywhere that contamination with ordinary dirt or soil is possible, particularly in substances contaminated with horse manure. From this fact it has been thought by some that it may multiply in the alimentary tract of the horse without causing harm and be spread about in this way. However that is, it is certain that such material is its most usual location, and therefore street dirt is an especially dangerous substance, as well as barnyard and stable soil, or earth fertilized by manure.

The resistance of the organism is another important consideration, for it excels other pathogenic organisms in its ability to withstand harmful agencies; this power is due to the spores it forms. Heating for 80 C. for an hour will not kill these spores, and they survive boiling for some minutes; they are correspondingly resistant to antiseptics. Spores are not destroyed by immersion in 5 per cent. carbolic acid for ten hours. Drying is without effect; splinters of wood covered with tetanus spores after being kept for eleven years have been found still capable of causing tetanus in mice.

From these facts we see that in the case of tetanus we have to do with an organism that is almost universally present, especially in ordinary street dirt, and that possesses great resistance to injurious agencies, and a long life under favorable conditions. These properties would make it a common infecting agent were it not for its strictly anaërobic nature, which limits the favorable opportunities for its growth, these favorable opportunities consisting in the introduction of the bacillus or spore into the depth of a wound so constructed as to shut out the air, and especially favorable if there is much injury to the tissues and a simultaneous infection with other bacteria. It thus becomes evident why there is no class of wounds so frequently followed by tetanus as those produced by blank cartridges. In them we usually find that one or two pasteboard wads have been driven deep into a hand or finger, often carrying with them a disc of the tough palmar skin, and this accident usually occurs in a person whose hands have been most thoroughly covered with street dirt in the process of vigorous celebration. At the same time the explosive force and the heat of the cartridge have led to much destruction of the tissues and hemorrhage, which furnish the remaining *desiderata*. Of course, mixed infection under these circumstances is certain to be added to assure anaërobic conditions. There has been some discussion as to whether tetanus bacilli are present in the blank cartridge wads or not; it really matters little, for without so direct an origin for the bacteria there remains the street dirt, which we know contains them. Wounds made by giant crackers and cannons are also more or less favorable sites for tetanus infection, according as they produce the conditions described above or not. When they cause much laceration and burning of the flesh they are not infrequently followed by lockjaw.

---

[1] The Jour. A. M. A., Aug. 29, 1903.

After infection has occurred the career of the organism and its means of causing the disease are quite characteristic and of the utmost importance in considering curative measures. Of the more common infections, diphtheria presents the closest analogy to tetanus, in that in both the bacteria remain quite strictly localized and cause harm by producing soluble poisons that are absorbed into the circulation. It is extremely seldom that the tetanus bacillus enters the blood or reaches remote organs; this has been recorded in the literature but five times, and so it becomes possible to stop the progress of the infection by removing the infected tissue. Furthermore, there are few, if any, fatal infectious diseases in which the number of bacteria is so small, for it is often difficult to demonstrate them with the microscope in the wound secretions or the tissues. Tetanus is, then, of all diseases characterized by a strictly localized infection, and an intoxication with a diffusible poison.

The poison produced by the tetanus bacillus, *tetanotoxin*, is formed in relatively large amounts in cultures, and is thus a favorable material for study; on this account it is the best known of the bacterial poisons and has been obtained more nearly pure than any other toxin. It has been estimated by Brieger that about one-three hundredth of a grain of this pure tetanus toxin would be a fatal dose for a man. Likewise, the manner of its action has been extensively studied, and there seems to be little doubt that the chief poison produced by the tetanus bacilli has a specific affinity for the ganglion cells of the anterior horns, with which it unites with such great firmness that it can not be readily separated again. One peculiarity of the tetanus toxin that attracted the attention of the early investigators was the length of time that elapses after its injection before the appearance of the first symptoms. If we inject diphtheria toxin or snake venom into an animal symptoms appear in a very few hours at the most, whereas in a guinea-pig it may be twenty-four or more hours before tetanic manifestations appear. This delayed action was very puzzling, and many hypotheses were advanced to explain it. During the past year what seems likely to be the correct explanation has been advanced by Meyer and Ransom.[2] From their experiments it would seem that tetanus toxin does not reach the spinal cord through the blood stream, but by slowly passing along the axis cylinders of motor cells from their terminations. Apparently the myelin sheath acts as a quite impervious membrane, and the toxin enters at the end of the neuron where it is not provided with this sheath. Sensory nerves do not transport the toxin to the cord. The toxin enters the nerve endings from two sources; the first is at the site of the infection, where the toxin is most concentrated, and this probably explains why tetanic spasms frequently begin in the vicinity of the infected part, or are most marked at this point. The rest of the toxin is taken up by the blood and lymph and distributed, to enter the motor nerve endings in small quantities all over the body, and by passing along the motor fibers to enter the cord diffusely, leading to the generalized spasms. The latent period that elapses after injection of the toxin before symptoms appear is occupied by the passage of the toxin along the motor fibers to the spinal cord; if the toxin is injected directly into the spinal cord symptoms appear at once. This also helps to explain the rather long incubation period observed in human tetanus, which is usually five to ten days. The first part of it is occupied by the growth of the bacteria and production of the toxins, the rest by the passage of the poison along the nerves to the cord. When the incubation period is brief it probably means that the bacilli are producing the toxin rapidly, so that in a very brief time enough is formed and transported to the cord to produce symptoms.

It also appears that other things that reach nerve cells follow the same route, including the tetanus antitoxin. Evidently, then, in a clinical case seen after tetanus has begun, the antitoxin injected at that time is a considerable distance behind the toxin in reaching the ganglion cell, which must have much influence in determining the results of the treatment. We will consider this factor at greater length when speaking of the antitoxin treatment of tetanus.

With the above facts concerning the pathology of tetanus at hand, let us consider, first,

THE PROPHYLAXIS OF FOURTH OF JULY TETANUS.

It goes without saying that the most desirable way to put an end to all this source of mortality is to prevent the wounds that begin the trouble. Abolition of blank cartridges and giant crackers would have reduced the number of deaths last year to less than twenty, and this is probably true of all other years. Display fireworks, such as Roman candles and rockets, caused but few tetanus infections, and so far as we could learn there were none from paper caps, torpedoes, and the small firecrackers. Surely these harmless forms of explosives ought to be sufficient for the entertainment of the children, and for "instilling patriotism" of at least equal value with the toy pistol and the cannon cracker. The work that physicians can do in their communities to lessen such evils of the Fourth is by no means inconsiderable, but having recently discussed this matter editorially[3] we shall limit ourselves here to discussing what can be done to prevent tetanus following such wounds as will be received this Fourth. As by far the most important wounds in regard to tetanus, and the most frequent, are those produced by blank cartridges, these are entitled to particular consideration.

Blank cartridge wounds form as deceptive a class of wounds as can be imagined. Usually they present simply a rather clean-cut perforation in the skin, about which are embedded many powder grains, for the wound is usually produced with the muzzle of the pistol but a few inches away from the skin. This is not a serious appearing wound, and if the boy's parents are not familiar with the danger he runs from tetanus they are likely to think that a simple dressing is all that he needs. And even if he is taken to a physician, too often the same opinion is expressed. History of several Fourths has shown that a very large proportion of the cases have occurred in boys who were seen by a physician soon after they were injured, and whose treatment had consisted solely in the application of a wet or dry dressing, or perhaps at the best a more or less ineffective attempt had been made to remove the wads. It is impossible, in the face of what we know about these wounds and their dangers, not to feel that many of these cases of tetanus would have been prevented by proper care of the injury when it was received.

The nature of the blank cartridge wound is primarily explosive. The chief damage is done beneath the skin.

---

[2] Discussed editorially in The Jour. A. M. A., Jan. 30, 1904.

[3] The Jour. A. M. A., May 21, 1904.

and the distance to which the injury extends is almost unbelievable unless one is familiar with these injuries. The force of the explosion follows particularly along the tendon sheaths and fascia when the wound is in the hand, as it usually is, and it is by no means uncommon for powder and dirt entering a wound of the finger to be found near the wrist, driven there along the tendon sheaths. The size of the channel formed by the explosion is usually smallest near the skin, and enlarges for some distance into the deeper tissue until the wads are reached, and there spreads laterally in a mass of bruised and lacerated tissue, blackened by fire and powder. The penetrative power of the wads is not generally appreciated, but is well illustrated by a case reported by Allen[4] of a boy who shot himself in the abdomen with a blank cartridge, and the wad not only perforated the wall of the abdomen and entered the peritoneal cavity, but so damaged the bowel that fatal peritonitis resulted. When the wound is in the palm of the hand, one of the commonest sites, the wad may pass between the metacarpal bones, and effects of the explosion will nearly always be found beneath the skin of the dorsum of the hand.

The surgical treatment of the wound must, therefore, be most thorough. Merely opening the wound and picking out the wads, even if followed by drainage, is evidently inadequate; and if we take into account that tetanus spores, even in the test tube, are not killed by 5 per cent. of carbolic acid in ten hours, it is evident that no amount of washing of the wound with antiseptics will assure safety from tetanus infection. Safety demands that every part into which dirt from the surface can have been blown be cleaned out, and so packed that air can enter and wound secretions escape. This requires anesthesia and careful dissection. The greatest difficulty in most cases will probably lie in the objections of the parents of the boy, and this must be met with instruction as to the dangers and the necessities of the situation. Allen and Ludlow, in a series of ten cases treated in Cleveland last Fourth by such thorough measures as above described, had no tetanus, whereas five cases treated superficially and sent in from outside the hospital all developed tetanus. Similar results have been obtained by many others, and Bain reports a very instructive case from the Massachusetts General Hospital, in which tetanus bacilli were found in the contents of a wound treated in this manner, yet tetanus did not follow. The basis of the treatment rests on the biology of the germs; they can not be destroyed by antiseptics, but must be removed mechanically as far as possible, and the site rendered unfavorable for the growth of any that may remain by removing all dead and injured tissue, by preventing mixed infection, and particularly by giving access of air to all injured surfaces. Loose packing of the wound with iodoform gauze is the best method of securing the last-named condition. Cauterization is not to be recommended generally, for we can not be sure in wounds of this nature that we reach all the bacteria, and if we fail in doing this we seal them in from the air most effectually. Most pernicious is the cauterization of the wound that has not been subjected to surgical exploration and cleansing.

Prophylactic administration of tetanus antitoxin is entitled to much serious consideration. Whatever may be said concerning the treatment of advanced tetanus by antitoxin, there is no room for doubt that as a preventive it is most efficient. We now possess numerous instances of its unquestionable value in checking epidemics of tetanus that have arisen in hospitals and maternities. Veterinary practice affords particularly convincing examples of its use in stables and veterinary hospitals where tetanus had become epidemic, and in which none of the protected animals was infected, whereas unprotected animals under the same conditions developed tetanus. During the past few years several physicians with large hospital practice have used the antitoxin prophylactically for Fourth of July injuries with complete success. Taylor of New York has treated many patients in this way without tetanus ever following in any.

We have been unable to learn of a single instance in which a person who had been given antitoxin soon after receiving a suspicious wound has developed tetanus. On the other hand, we have not learned of any harmful results from its injection into persons not infected with tetanus. It therefore seems safe to assume that a person who receives a prophylactic injection of tetanus antitoxin will be protected against tetanus, and will not be injured by the procedure. How necessary it may be to give antitoxin when the wounds are treated thoroughly by surgical means within a few hours after they are received may be a matter for discussion, but it can hardly be denied that its administration ensures almost absolute safety and will do no harm. In those cases in which the physician sees the wound only after one or more days have passed, or when, because of unconquerable objection on the part of the patients or the parents, or other reason, it becomes impossible to make sure both of the cleansing of the wound and the absence of any toxins already formed and absorbed, there can be no question of the necessity of the prophylactic use of antitoxin.

Tetanus antitoxin is prepared by the same firms that prepare diphtheria antitoxin, and also by the New York State Department of Health, and is on the market in a similar form. The chief difference is that the dose is not measured by units, but generally by cubic centimeters. For prophylactic purposes 10 c.c. should be injected in the same manner as diphtheria antitoxin, best in the vicinity of the wound if possible, and, according to Meyer and Ransom, best into the muscle if the wound is in a fleshy part. This should be done immediately after the wound is cared for if the antitoxin is at hand, but if not it can be used with profit at any time that it can be obtained within the next several days, since the period of incubation is so long. Where facilities for microscopic examination are available, it is advisable to have smears made of the wound secretions, and, if possible, cultures. While a negative finding does not assure an absence of bacilli, their demonstration would be indication for most vigorous use of antitoxin for several days, until the period of danger is past. In all cases in which the wound is or becomes infected with pus bacteria a second dose of the same size should be injected three or four days later. Only in simple cases with perfectly clean wounds should one be satisfied with a single injection. If the patient is quite young, under 8 years, 5 c.c. doses should be adequate.

CURATIVE TREATMENT OF TETANUS.

An apparent mortality of over 95 per cent. in the Fourth of July tetanus of 1903 indicates the futility of the methods generally employed. This class of cases seems to offer the worst prognosis of any of the forms of tetanus. Presumably the reasons for this are the youth of the patients and the unusually favorable conditions offered the bacilli by the blank cartridge wounds, so that their multiplication is rapid. It is also to be borne in mind that antitoxin was used in a considerable proportion of the fatal 95 per cent. On the face of these returns it may seem that antitoxin is useless, but there are many reasons for believing that better results are possible through its use than have yet been obtained *without it.*

---

[4] Cleveland Medical Journal, December, 1903.

In spite of its great experimental efficiency in animals, and its great prophylactic value, tetanus antitoxin as ordinarily administered has so far produced anything but a favorable impression as a curative agent after tetanus has once manifested itself. To be sure, large collections of figures have been made from the literature giving somewhat better results with antitoxin than without, but the value of such statistics is always questionable because patients with tetanus who recover are more likely to get into the literature than are those who die. On the other hand, the antitoxin has a very distinct and marked power of neutralizing tetanus toxin in the test tube, and also in the bodies of animals when the two substances are in the circulation at the same time. Evidently, then, since tetanus antitoxin can neutralize the toxin when once an opportunity for contact occurs, it has possibilities as a curative agent. The reasons for the usual failure and the possibilities for improvement rest on certain peculiarities in the mechanism of the action of tetanus toxin.

Diphtheria antitoxin possesses curative properties because a considerable part of the toxin is free in the blood, and also, perhaps, because the union of toxin and cells is not so firm that an excess of antitoxin is unable to withdraw the toxin from the cell to unite with the antitoxin. On the other hand, tetanus toxin when combined with nerve cells is either so firmly combined with them that it can not be separated by an excess of antitoxin, or else, as Meyer and Ransom's work indicates, the antitoxin may not reach the nerve cells in any considerable quantities for some time after it is injected.

It must be remembered that when a patient develops tetanic spasms, which is the earliest time at which tetanus can be diagnosed, the disease has been in progress from five to twelve days as a rule. During that time the bacilli have first multiplied, then produced toxin, and, lastly, probably requiring a considerable portion of the incubation period, the toxin has been diffusing along the axis cylinders of the motor nerves and accumulating in the motor ganglion cells until concentrated enough there to give rise to spasms. As before mentioned, there is reason to believe that many if not all substances that reach the body of a nerve cell enter chiefly at the extremities of its processes rather than from the periphery of the cell body proper, and Meyer and Ransom's work suggest that this is true also for tetanus antitoxin as well as for the toxin. This does not, of course, exclude the entrance of more or less of these substances more directly into the cell. Now, if antitoxin is injected subcutaneously into the body of a person with tetanus, it must, if this is true, follow the route taken by the toxin along the nerves perhaps two or more days before. There will, therefore, be at least that much interval between the time of injection of antitoxin and the time that it can reach the point where the toxin does its harm, during which time the nerve cell is saturated with the toxin and seriously damaged. As nerve cells have peculiarly slight power of repair, even if the antitoxin were then able to separate the toxin from the cell, fatal injury may have been done. A person who has manifested the classical symptoms is really in the last stages of the disease, a time when we would not expect much even of diphtheria antitoxin. It may be, then, that we shall not ever be able to realize much better results from tetanus antitoxin; but even at the worst it is distinctly indicated for the purpose of neutralizing the toxin that still exists free in the circulation, and thus prevent any further intoxication *than already exists. Considering the facts stated before,* concerning the pathology of the disease, and the sum of the experience of those who have attended cases of tetanus, the proper procedure in caring for a case of tetanus in which spasms have already appeared seems to be as follows:

As soon as possible after the patient is seen general anesthesia should be produced, and the wound cleaned out most carefully in order to put an end to further formation and absorption of toxin. This can be done effectively because in tetanus the bacilli are localized quite strictly in the wound area. Every shred of necrosed tissue must be removed, not to mention the wads, which are often two in number. The treatment will, of course, be similar in wounds from other causes. Free drainage and access of air should be secured by loose but complete gauze packing; there are some reasons for believing that iodoform gauze is of advantage. Care must be taken after the operation to secure proper sterilization of the instruments and cloths contaminated by the wound, with due consideration for the resistance of tetanus spores. Boiling of instruments in soda solution for one hour is sufficient, and sheets, etc., may be sterilized before being handled by being soaked several hours in a tub containing 1/1,000 bichlorid solution, with enough hydrochloric acid to make ½ per cent., the acidity increasing by many times the bactericidal powers of the bichlorid.

Before consciousness returns, and perhaps even before the operation is begun, the antitoxin should be administered if available. By far the best results that have been reported seem to have been obtained by those who have injected the antitoxin into the spinal canal. As tetanus affects particularly the anterior horns of the spinal cord, this seems much more logical than the intracranial injection, and it has the great advantage of not adding a considerable operation to the already critical condition. The method used is to introduce the needle of the antitoxin syringe, preferably one of fairly large caliber, into the subarachnoid space by passing between the third and fourth lumbar vertebræ, in the usual manner followed in performing lumbar puncture. The syringe must not be attached to the needle at this time, but after the needle has entered the subarachnoid space the cerebrospinal fluid should be permitted to escape in quantity up to 150 drops, if that much will come. This is done to remove as much as possible of the cerebrospinal fluid, which is known to be highly toxic in tetanus, much more so than the blood serum. Then the syringe, containing 10-15 c.c. of antitoxin, should be attached to the needle and its contents slowly injected, allowing at least five minutes for the process of injection. No harm need be feared from the injection of this amount of fluid, for much more has been injected without causing any trouble whatever. This should be followed by injection with a fine needle of as much as possible into the substance of and along the course of a large nerve trunk, preferably the one supplying the injured part—of course, before the patient comes out of the anesthesia. This method is based on the newer observations above cited concerning the paths by which the antitoxin reaches the spinal cord. As these observations are new, this method has not been given extensive trial as yet, but in the four cases we have found recorded of its application all recovered.[5] Because of its indication on experimental grounds it should by all means be given a thorough trial. And lastly, still another 10 c.c. may be injected in the vicinity of the wound. One need have no fears about using too much antitoxin. Elting[6] reports a case in which one patient recovered after receiving 80 c.c. of P., D. & Co.'s antitoxin, 100 units of Behring's dried antitoxin, and 1,050 c.c. of the New York State Department of Health antitoxin subcutaneously, besides 150 c.c. of the latter intraspinally—altogether over 1,300 c.c. (about three pints). In one period of twenty-four hours he injected 300 c.c. subcutaneously and 50 c.c. intraspinally.

---

[5] The first use of this method reported in America is by Rogers, Med. Record, May 21, 1904, and the patient, a boy injured with a blank cartridge, recovered.

After the operation and injections a subcutaneous saline infusion is desirable, because much fluid is needed by the patient, and it is difficult to feed a patient without adding to the sources of irritation. The patient should then be placed in a quiet, darkened room, with deadened floors, and complete plugging of the ears is advantageous. Every possible means should be taken to avoid any disturbance which may start up spasms. For this purpose morphin, chloral and bromids should be exhibited, sufficient, if possible, to keep the patient stupid. For the first twenty-four hours feeding should be limited as much as possible for the same reason, but after that time it needs to be pushed, as there is great exhaustion. The nourishment must be liquid, and usually has to be fed through a tube. Rectal alimentation is valuable if it can be given without too great disturbance.

Twelve hours after the first injection the patient should be again lightly anesthetized to avoid irritation and the process of withdrawing cerebrospinal fluid and introducing 10-15 c.c. of antitoxin again repeated, with also 10 c.c. subcutaneously, and, if thought desirable, more saline infusion. After this the subarachnoid injections, always preceded by the withdrawal of cerebrospinal fluid, should be repeated every twenty-four hours as long as indicated.

The above-described course of treatment can be realized fully, of course, only in places where the best of facilities are obtainable. Where antitoxin is not procurable the method will be much the same with the exception of the injection of the serum. As a substitute for antitoxin many European physicians, particularly the Russians, are using emulsion of fresh brain tissue, on the principle demonstrated by Wassermann that brain tissue has a specific affinity for tetanus toxin. He found that if brain emulsion and toxin were shaken together and then sedimented, the toxin would all be removed from the supernatant fluid and combined with the brain tissue in a harmless form. Experiments also indicate that a similar union can occur within the bodies of infected animals. The method employed is to remove, under aseptic precautions, the brain of a freshly-killed rabbit, pig or sheep, and make an emulsion of 10-15 grams (one-half ounce) in about 30 c.c. (one ounce) of sterile salt solution. After straining through sterile cheesecloth under slight pressure, this is injected subcutaneously, near the wound if possible, and repeated every day as long as indicated. This can merely be expected to neutralize toxin that has not entered the nervous system, but the Russians report excellent results—13 recoveries in 16 cases are reported by Krokiewicz.[7]

Baccelli's carbolic acid treatment is used by the Italians particularly, but has had quite general application. The results outside of Italy do not seem to have been particularly striking, but it has sufficient reputation to warrant its use when other methods are not available. It simply consists in injecting subcutaneously 1 per cent. carbolic acid solution, in sufficient quantity so that about five grains of the acid is given an adult during twenty-four hours. There seems to be remarkably little injury produced by the carbolic acid—as high as 144 grains a day having been used in the same way in plague.

Dr. S. A. Matthews[8] has published a method of treatment by a special salt solution that is very effective in experimental animals. The salt solution has much effect in washing materials out of the tissue cells, "cell catharsis," Matthews calls it, and produces a most profound diuresis. On this last account, at least, if for no other reason, it is to be recommended, and as the solution is entirely harmless it is well worthy of a thorough trial, particularly in the cases in which antitoxin is not available. It can readily be prepared by the following formula:

Sodii chloridi	gr. 55.5	3	656
Sodii sulphatis	gr. 155	10	06
Sodii citratis	gr. 51	3	364
Calcii chloridi	gr. 2		136
Aquæ	pints 2	1000	

This may be injected intravenously very slowly, not over 3 c.c. (1 dram) per minute, in quantities up to 500 c.c. (1 pint) at each infusion, which should be performed twice the first twenty-four hours, and once each succeeding twenty-four hours. The profound diuresis that this solution produces must have greater or less beneficial effect, and it is probable that the calcium reduces the muscular spasms.

In the great number of cases of Fourth of July tetanus that this country is presumably doomed to see this year, there is a great opportunity for therapeutic study. Probably much of our lack of success in the treatment of tetanus lies in the relatively rare occurrence of this disease, so that no one person is able to accumulate much personal experience with its management. If each isolated case, however, were carefully recorded the large total would undoubtedly afford valuable material on which to base future treatment. We therefore ask our readers who see cases of tetanus this year to send us clinical reports of the cases and their treatment, whether successful or not. If this is done by a considerable number, the reports can be profitably put together and analyzed, perhaps with much benefit.

Medical Saline Solution.—It is customary among physicians and physiologists to refer to the physiologic 0.6 per cent. salt solution as "normal saline solution." The *Pharmaceutical Journal* claims that this is liable to be confounded with the chemist's normal volumetric solution of sodium chlorid which has occasionally been supplied for physiologic purposes when normal saline solution was asked for. In one case the patient died; in the other, the result is unknown. Physiologic salt solution is usually wanted in a hurry, and it is likely that in the confusion such an error might be made. As the chemical normal saline solution is nearly ten times as strong as the physiologic solution, disastrous results are likely to happen. Since this chemical saline solution is but one of a series of volumetric solutions, each of which are styled "normal," chemists can hardly be asked to change the name. It would, therefore, be better for physicians not to use the term "normal" saline solution, as applied to the 0.6 per cent. solution of sodium chlorid for physiologic purposes, and to adhere carefully to the term "physiologic" or "medical" salt solution.—*Practical Druggist.*

SATURDAY, JUNE 18, 1904.

THE ATLANTIC CITY SESSION.

The fifty-fifth annual session of the American Medical Association, held last week, was the most successful of any held in the history of the Association, not only in the number in attendance, but in the scientific work accomplished.

The attendance excelled that expected by the most hopeful. With the exception of one of the international medical congresses, it was probably the largest gathering of medical men ever held anywhere, the registration numbering 2,890. At the meeting in Atlantic City in 1900, 2,019 registered: at St. Paul in 1901, 1,806; at Saratoga Springs in 1902, 1,425, and at New Orleans in 1903, 2,006. Yet in spite of the number in attendance there was no evidence of crowding and no criticism in regard to accommodations. Atlantic City certainly proved herself capable of entertaining in a most satisfactory manner. The local committees of arrangement had done their work well, and are to be congratulated on the arrangements made and on the successful outcome of this magnificent meeting.

From a scientific point of view, no meeting ever surpassed it, whether we consider the meetings of special societies, international congresses, or what not. Every year some sections report having done very superior scientific work. This year from all the sections comes this report. It is not only the section officers and those especially interested in the sections who are saying this, but those who have never before taken an interest in the sections and who are more directly interested in other societies than in the sections of the American Medical Association are also acknowledging the superior scientific work at Atlantic City. The section officers deserve great credit for this result of their year's efforts. The officers of each section have vied with each other in trying to outdo what has been done in the past and to produce a program that should be superior scientifically to that of any preceding year and to that of any other special society. Those who know the amount of labor necessary to get up such a program and to make a section successful will appreciate that all the section officers have worked hard and have done their duty faithfully. They have all set standards for their successors that will be hard to surpass.

The symposia following the orations on Tuesday, Wednesday and Thursday evenings were something entirely new with this session, and they proved to be valuable as well as attractive. Never before have the general meetings been so well attended. The symposium on the first evening, which was devoted to a description of the research work that is being done in several institutions in this country, was a revelation to those who did not know how much of this work was being done. The symposium on Wednesday evening, on the relation of the medical services of the Government to the profession, was also most interesting and instructive. Such a symposium tends to bring the profession and the services together as nothing else can. We all realize, to a certain extent at least, what the U. S. Public Health and Marine Hospital Service and the Medical Department of the Army have done and are doing, but we have been very unfamiliar with the work of the Medical Department of the Navy. Surgeon Stokes, in his part of the symposium, showed that the medical officer of the Navy has a wider field of usefulness than is usually supposed. The last symposium, that of Thursday evening, was also valuable and instructive, and brought to the attention of the profession other work that is being done by the Government that is of special interest to medical men. While the building in which these meetings were held was a large one, standing room was at a premium on each occasion. President Musser deserves the thanks of the profession for having arranged for these symposia, and those who took part in them are also entitled to thanks for what they did to make them so successful.

THE INFLUENCE OF HEREDITY IN CANCER.

Of all difficult problems in medical statistics, none offers more obstacles or shows more indecisive results than the figures compiled to ascertain the influence of heredity on the occurrence of malignant tumors. What with ignorance of patients concerning their family history, and the greater tendency among those with cancer to look up and know about the family record in this respect than among the non-cancerous, beside many other sources of error, there arise serious difficulties in the way of arriving at conclusions that are of real value. For this reason we find authorities differing most widely in their estimate of the importance of hereditary influence. There are those who are convinced that heredity is of great moment, and those who do not believe inheritance plays any part in the occurrence of cancer, beside still a third class, who, although recognizing inheritance as a factor in the etiology of cancer, do not consider it worthy of much attention. As cancer is practically never present at birth nor soon after, it evidently is not transmitted as a distinct disease, but at the most only a "predisposition" is inflicted on the offspring of cancerous progenitors. Now, while there can be no denying that occasionally we see instances in which an undue proportion of one family succumbs to cancer, yet there are other possible explanations than an inherited tendency. Advocates of the parasitic origin of cancer will suspect that the members of the family have been exposed in common to the infectious agent, or possibly have infected each other, much as some explain the frequent occurrence of a high tuberculous morbidity in a given family. The "cancer house" endemics will also fall under the same charge. On the other hand, it may be claimed that such cancerous families may be accounted for by the laws of probabilities—that there are enough cases of cancer occurring throughout any population so that there are bound to occur at times certain groupings of the cases, which may at one time fall on a family, at another on a house, or a block, or a village.

The earlier investigators, as a rule, seem to have attached much importance to heredity. In 1857 Paget studied the histories of 411 patients, and came to the conclusion that the respective probability of hereditary transmission of cancer was 22.4 per cent. for those with relatives having cancer, and but 8.2 per cent. for those without cancerous relations. These figures have in the following years had much influence in favoring general belief in the hereditary taint. Virchow in his famous "krankhaften Geschwülste" in 1863 accepted as certain the existence of inherited predisposition to cancer. Lichtenstern's statistics from 1,137 cases showed a cancerous family history in 17 per cent. Roger Williams in 1892 found an apparent liability of cancer in those with cancerous relatives 10 per cent. greater than in those without cancerous relatives. Other statistics of similar periods do not give so high an inheritance tendency, figures of 8 per cent. to 10 per cent. being obtained by many, and, as similar figures have been obtained by inquiry into the history of patients without cancer, these writers, as a rule, question the existence of an inherited predisposition to cancer that is sufficiently marked to be of any practical importance.

Three thousand cases of cancer recorded in the Middlesex Hospital have been carefully investigated, and. after proper eliminations, have been studied by Prof. Karl Pearson[1] by biometric methods, with construction of "skew curves," etc. From these, which are probably as valuable investigations as any recorded, it would seem that there is almost no appreciable difference in the incidence of cancer in those with and those without known cancerous relatives. Out of 2,368 female cancer patients, 359 had and 2,009 had not a family history of cancer. Out of 753 female patients with diseases other than cancer, 102 had and 651 had not a family history of cancer; or, approximately, 15.1 per cent. of family cancer among the cancerous against 13.5 per cent. among the non-cancerous patients in the same hospital. In considering these results, however, it must be taken into consideration that a certain number of these non-cancerous females might later develop cancer, thus making the figures slightly, but not greatly, different. This error may be offset by the greater likelihood of cancerous patients having acquainted themselves of other cases of cancer in their families than is likely among the non-cancerous. In any event, however, it may at least be concluded that inheritance is probably not as important a factor in cancer as some authorities have believed, and there is, indeed, a large possibility that it is really of little importance at all. Certainly there is no ground in these figures for people with cancerous relatives to be particularly alarmed concerning their liability to the same disease.

Another interesting fact brought out by these tables is that females have cancer at an appreciably earlier age than do the males, for among 2,368 female and 632 male cancer patients the mean average age of the onset of symptoms was, in the former, 47.822 years, and in the latter 53.358 years. The modal age, which is a more proper basis for considering the most common time of occurrence, gives an even greater difference, being respectively 46 to 55 years, a difference of 9 years in favor of the males. The question of the influence of tuberculosis in the family history on the occurrence of cancer was also investigated and found to amount to practically nothing; whatever difference was found, was slightly in favor of tuberculous families not having cancer.

THE CHEMISTRY OF THE URINE IN DISEASES OF THE PANCREAS.

In a recent editorial[1] we called attention to the important work of Robson and Cammidge on the diagnosis of pancreatic lesions. In view of the important work of Hewlett,[2] we deem it worth while to again call attention to this subject, and particularly to the chemistry of the urine in these cases.

The chemical aspects of Robson's cases were worked out by Cammidge, and a brief description of the test which he has devised will not be amiss. Starting out with the idea that fat-necrosis is the most constant and typical lesion of pancreatic disease, Cammidge reasoned that as a result of this there are probably secondary changes in the blood, and perhaps in the urine. Knowing that in fat-necrosis glycerin is set free and absorbed into the circulation, he endeavored to isolate this substance from the blood, but was unsuccessful in this on account of the small quantities of blood which could be obtained and the small quantity of glycerin in them. He then turned his attention to the urine, and was able in every case of pancreatic disease to isolate a substance which he regards as a glycerose. It is not our purpose to criticize here the chemical aspects of Cammidge's work, for, even though his chemical interpretation be erroneous, and there is good reason to believe that it is, the fact remains that a substance can be found in the urine of pancreatic disease which is not, with few exceptions, found in other diseases. Without going into detail as to the technic of his tests, it may be stated that they are relatively simple, the main test being based on the fact that glycerin, when heated with a dilute mineral acid, produces a glycerose which can be thrown down in crystal form by phenylhydrazin. As a result of a large series of tests on cases of pancreatic disease and other conditions, Cammidge has been able to formulate quite accurately the applicability of his test, and also its limitations. He shows that the crystals found in pancreatic disease may also be thrown down in other conditions, as pneumonia, adenitis, and cancer, but that a certain modification of his original test, and certain peculiarities in the crystal solubility, serve to largely, though not entirely, eliminate these sources of error. The modification of his original test consists of a preliminary treatment of the suspected urine with perchlorid of mercury, which has the effect of preventing the crystal formation in cases of acute pancreatitis, but not in carcinoma of the pancreas and the non-pancreatic diseases associated with crystal formation. Tests to determine the time which is required for the dissolution of the crystals by dilute hydrochloric acid are also of great value in differentiating pancreatic conditions. Thus the crystals formed in cases of acute pancreatitis undergo solution in the acid much more rapidly than those formed in chronic pancreatitis, and the crystals formed in chronic pancreatitis dissolve more quickly than those formed in cancer of the pancreas. The author sets time limits on these changes, which he states are reasonably accurate, and also describes certain differences in the size of the crystals in different diseases, which, though less constant, are of value. In summing up, Cammidge concludes that the test, while open to fallacies, is of considerable value; in the absence of crystal formation, pancreatic disease is excluded entirely, and by following his directions, which are carefully given, the less absolute forms of the test are of considerable use.

[1] Jour. A. M. A., April 30, 1904.

[2] Jour. of Med. Research, vol. xi, No. 2.

The work of Hewlett, while purely experimental, also seems likely to prove of benefit in clinical cases. Like Cammidge, he started with the idea that fat-necrosis, being the most constant lesion of pancreatic disease, chemical changes in the body fluids should accompany it. Unlike Cammidge, he searched for the substance causing fat-necrosis rather than those resulting from it. His experiments had in view the possibility of finding in the urine in pancreatic disease, lipase, the fat-splitting ferment, a possibility already suggested by a single recorded case of Opie. In the urine of dogs in which he had produced an experimental pancreatic lesion, Hewlett was constantly able to detect lipase in appreciable quantities by testing the splitting power of the urine on ethyl butyrate. His work showed that lipase is absent, or present in very small quantities, in normal urine. As a result of various insults to the pancreas, but particularly as the result of acute hemorrhagic pancreatitis, lipase appears in the urine in easily demonstrable quantities. It is also found over a period of four or five days following ligation of the pancreatic duct. Both of these researches open up great possibilities in the way of diagnosis of pancreatic disease. Before we can definitely judge of their value, however, they must be tried in a very large number of cases. So far as we can judge at present, it seems likely that the lipase test will prove of most service in acute pancreatic conditions, and Cammidge's test in chronic conditions.

BACTERIA IN NORMAL TISSUE.

It is held that the organs of the body normally are sterile; in fact, this is the principle on which asepsis in surgery and medicine is supposed to be based. There has accumulated considerable evidence, however, that this apparently fundamental postulate must be essentially modified. It has been generally conceded that bacteria can pass through an ulcerated or abraded intestinal mucosa or other epithelial surface, but an intact surface is supposed to be an efficient barrier to the entrance of germs.

Adami[1] injected the colon bacillus intravenously into animals, and in 15 minutes these organisms were found in the cells of the liver and kidney. In two or three hours later the organisms appeared as diplococcoid forms and often arranged in the cells in a characteristic manner. This diplococcus appearance is due probably to the disintegration of the bacteria by the tissues of the body. Organisms may be seen frequently in the intestinal or mesenteric lymph glands and many hold that they are constantly present in these places. In cirrhosis of the liver Adami observed small granular bodies often in diplococcoid arrangement in the liver cells, which were at first taken for pigment. Later he found these bodies present in practically all livers taken at autopsy and considers them bacteria undergoing destruction. Bodies similar in appearance have been found in normal kidneys also.

Nicholls[2] describes a method of observing bodies which he considers bacteria in the mesentery of normal animals. After removing the epithelial cells on both surfaces by means of a swab, he cuts out a small piece of the mesentery under strict aseptic precautions. This tissue is then stained in carbo-thionin, cleared and mounted in balsam. About the cells in the mesentery he observes bodies often in diplococcoid form and arranged very characteristically around the nuclei of cells near the capillaries. These bodies he considers bacilli absorbed from the intestinal tract and modified by the digestive action of the tissues. He also reports cultures obtained from perfectly normal livers and kidneys of animals removed under the strictest aseptic precautions.

While these results require further confirmation and more extended investigation, the possibility of bacteria being taken into the body and distributed in various organs is certainly an interesting subject and may throw some light on the numerous infections which so often originate in some unexplained manner in various parts of the body. As Adami expresses it, the organs are not actually but only potentially sterile, the bacteria being carried to them continually, and in health undergo a rapid disintegration. If the resistance of the body is lowered or an excess of germs invade the organs, or if the virulence of the bacteria which normally enter the body such as the colon forms should increase, an infection might result. This may be the true explanation of the so-called cryptogenetic septicemias, terminal infections, idiopathic fevers and the like.

THE PATENT-MEDICINE MEN ACTIVE.

The patent-medicine men are doing their best to counteract the impression made on the public by the recent utterances of Mr. Bok in the widely circulated *Ladies' Home Journal.* Beside the suits that have been started against him and the journal, a circular has *been sent out to druggists, and there are other evidences of increased activity on the part of the manufacturers.* Undoubtedly this agitation will invigorate the opposition to the Pure Food Bill when it comes up before the Senate next session, and it behooves the medical profession to do its best to prevent these influences having their effect. If we are idle, the opposition is not. We may find that many votes have been pledged against the bill through the personal work of the patent-medicine manufacturers and others interested. We should relax no effort during the interim of the session of Congress to insure the passage of the Hepburn act, which was laid over at the last session of the United States Senate.

RATTLESNAKE ANTIVENIN.

Although the death rate from snake poisoning in this country is insignificant as compared with that of India and other tropical countries, snake bites are sufficiently frequent and sufficiently harmful to render a knowledge of snake venoms and their antidotes of great practical value. The variety of poisonous snake most widespread in America is the rattlesnake, and the recent studies of Flexner and Noguchi[1] deal mainly with this snake and its poison. When Calmette of Lille first published his classical researches on snake venom and antivenin it was thought that he had produced a substance which would neutralize all forms of snake poisoning. The researches of recent years have shown, however, that the poisonous principles in the venom differ in different serpents. Thus the active principle in cobra venom is a neurotoxin, while that of rattlesnake venom is a substance which destroys the endothelial cells lining the blood vessels, allowing the escape of the blood—technically speaking, a hemorrhagin. The effect of this hemorrhagin on the tissues is intensely destructive, and the extensive local necrosis resulting from its introduction has interfered up to the present with the immunization of animals to rattlesnake poison. Flexner and Noguchi have been able to overcome the disagreeable local effects and at the same time retain the hemorrhagin in a form in which it is able to set up reactive processes in the animal body, with the resulting production of an antivenin. These results give us every reason to believe that in the near future a serviceable rattlesnake antivenin will be on the market, in which case it is to be hoped that the popular but unscientific treatment of rattlesnake poisoning with massive doses of spiritus frumenti will be superseded.

THE RELATION OF SUBINFECTION TO PERNICIOUS ANEMIA.

While the gross and microscopic pathology of pernicious anemia has been cleared up to a large extent, especially by the work of Warthin, we still seem to be in the dark as regards the etiology of the disease. The view most commonly held is that which assumes the condition to be due to the absorption of bacterial toxins from the intestinal canal, a conception which is opposed by the well-known fact that, at any rate in the usual intestinal bacteria, the colon group, the toxin is not soluble, but is situated in the body of the bacillus itself. In a recent article Charlton[1] reports some very interesting work carried on in Adami's laboratory which has a bearing on this subject. The suggestion made by Adami in 1889 that pernicious anemia was probably due to latent infection or subinfection with intestinal bacteria formed the starting point of the research. Rabbits were injected at stated intervals with sublethal doses of colon bacilli obtained from the intestinal canal of other rabbits, and this was kept up for some time. It was noted that the rabbits so treated developed an anemia which in some respects resembled the pernicious anemia of man. If the colon injections were discontinued early the animals recovered, but if they were kept up the animals frequently developed in the late stages of the disease spinal cord symptoms which examination showed were due to degeneration affecting mostly the posterior columns of the cord. Similar lesions could not be induced by injecting rabbits with killed or filtered cultures of the colon bacilli. Cultures which had been acted on by pepsin did not differ in their action from ordinary living cultures. In discussing the significance of these observations, the author suggests that the fact that an anemia so closely resembling pernicious anemia can be produced experimentally by subinfection strongly supports the view that pernicious anemia is due to the same cause. Expressed in the author's own words, the mechanism would be "the repeated entry into the system of micro-organisms which, while they do not proliferate, as in infections proper, nevertheless, by their presence and by the products liberated in their destruction, have an eventual deleterious effect on the tissues."

Medical News.

[To give the minutes in this issue, the amount of space given to news, editorials and other departments is reduced.]

ILLINOIS.

Hospital Dedicated.—With elaborate ceremony the addition to St. Francis Hospital, Freeport, erected at a cost of $47,000, was dedicated by Archbishop Quigley, June 8.

Personal.—Dr. Richard D. Dugan has been appointed president of the Illiopolis board of health.——Dr. Lucian L. Leeds entered on his fiftieth year of practice in Lincoln, June 4.

Hospital Staffs Named.—The following are announced as the consulting and general staffs of the Rockford Hospital: Consulting staff—Drs. William H. Fitch, Albert S. Green, Walter

---

[1] Journal of Medical Research, vol. xi, No. 2, 1904.

B. Helm, Frank H. Kimball, Daniel Lichty, and Henry Richings; general staff—Drs. Robert C. Bourland, Frederick W. Calkins, Sanford R. Catlin, Robert E. Coy, Thomas R. Culhane, Arthur F. Comings, William R. Fringer, J. Henry Frost, Roscoe G. W. Kinder and George L. Winn.

Chicago.

Dr. Davis Ill.—Dr. N. S. Davis, Sr., has been ill at his home for a week. His condition is rendered serious because of his advanced age.

Low Mortality.—For the week ended June 11, a total mortality of 420 was reported, an annual rate of 11.4 per 1,000. The lowest previous rate was 12.1 per 1,000.

Personal.—Dr. Alexander C. Wiener has gone to Europe for the summer.——Dr. Bartholomew F. Flanagan, first lieutenant and assistant surgeon, Illinois N. G., assigned Seventh Infantry, has resigned.——At the commencement exercises of the University of Illinois, June 8, the degree of doctor of laws was conferred on Dr. William E. Quine.

MARYLAND.

Crusade Against Variola.—The board of estimates has allowed the health commissioner of Baltimore $6,500 from the contingent fund to fight smallpox. This will be used chiefly to pay the extra vaccine physicians.

Many May Deaths.—During May 869 deaths were reported in Baltimore, 115 more than for May, 1901, 65 more than in May, 1902, and 116 more than in May, 1903. Tuberculosis caused 143 deaths; pneumonia, 90; heart diseases, 73; Bright's disease, 52; cancer, 46, and apoplexy, 45.

Personal.—Dr. Herbert L. Rich, professor of chemistry in the Western Maryland College, has been elected school physician and sub-master in chemistry in the Jacob Tome Institute, Port Deposit.——Dr. R. B. Whitridge, Baltimore, sailed to Germany June 2.——Dr. Leonard K. Hirshberg, Baltimore, has been awarded the Fisk Prize of $250 by the Rhode Island Medical Society for scientific research on the application of light as a therapeutic agent. There were over 200 competitors.——Dr. Edward W. Altvater, Upper Falls, has retired from practice on account of ill health, and will reside in Baltimore.——Dr. Arthur G. Barrett, health warden for the Fifteenth Ward, has resigned and has been succeeded by Dr. William Caspari, Jr.

MASSACHUSETTS.

The death rate of Boston for the week ended June 11 was at the annual rate of only 14.17 per 1,000, an unusually low record.

Personal.—Dr. George F. Dow, Reading, surgeon, and Dr. Herman W. Gross, assistant surgeon of the Sixth Regiment, M. V. M., have resigned.——Dr. Leonard Huntress has been appointed a member of the Lowell Board of Health.——Dr. Arthur F. Weston, house surgeon at Malden Hospital, was recently operated on for appendicitis, and is doing well.——Dr. Thomas J. Garrigan entertained the Brookfield Medical Club, May 18, in celebration of the twenty-eighth anniversary of his entry in practice.——Dr. Walter T. Bowers has been reelected president of the board of trustees of Clinton Hospital.——Dr. David D. Brough has been made chief medical inspector of the Boston Health Board.

State Society Meeting.—The one hundred and twenty-third annual meeting of the Massachusetts Medical Society was held in Boston June 7 and 8. The Shattuck Lecture was by Dr. George S. Huntington, New York City, on "The relation of comparative anatomy to medical education and practice." In the annual discourse, Dr. Harold C. Ernst, Boston, offered some timely suggestions regarding modern medical education. About twelve hundred fellows sat down to the dinner in Mechanics' Hall, and later were addressed by Bishop A. H. Vinton of Western Massachusetts, and the Hon. Carroll D. Wright. Dr. H. D. Arnold outlined a plan by which the Boston Medical Library is to assume the functions of an academy of medicine. Dr. Arthur T. Cabot of Boston was elected president. Dr. George W. Gay, Boston, vice-president; Dr. Edward M. Buckingham, Boston, treasurer; Dr. Charles W. Swan, Brookline, corresponding secretary; Dr. Francis W. Goss, Roxbury, secretary, and Dr. Edwin H. Brigham, Boston, librarian. It was unanimously voted that a cordial invitation be extended to the American Medical Association to meet in Boston in 1906.

NEW YORK.

Personal.—Dr. Samuel B. Ward has been elected dean of the Albany Medical College, vice Dr. Albert Vander Veer, resigned.

New Hospital at Fordham.—The trustees of Bellevue and the Allied Hospitals have purchased a plot of ground equal to four city lots from the Jesuit Fathers of St. John's College. The erection of the hospital will be begun at once.

State Shows a High Death Rate.—The bulletin of the State Board of Health shows that in the past four months of 1904 there were 53,000 deaths in the state, 8,500 more than for the same months of 1903, and nearly 10,000 more than for the same period of 1902.

New York City.

Spinal Meningitis Decreasing.—The records show a great falling off in the mortality from this disease. Since March 1 there have been 700 deaths in greater New York and 411 in the Borough of Manhattan.

Personal.—Dr. Floyd J. Metzger has been appointed assistant in general chemistry, Dr. John D. Walker clinical lecturer in surgery, and Dr. Lucius W. Hotchkiss, clinical lecturer and instructor in surgery at the college of Physicians and Surgeons.——Dr. and Mrs. J. Duncan Emmett have returned to New York and expect to remain in the city until July 1.

New Building for Medical School.—The New York University has decided to purchase land adjoining the new Bellevue Hospital Medical College and to erect there a six-story building for clinics and laboratories. The first floor will be given up to the free dispensaries of the college, which treats more cases than any other clinic in the city excepting one. During 1903, 150,000 patients were treated.

Contagious Diseases.—For the week ended June 24, 1904, there were reported to the sanitary bureau 1,042 cases of measles, with 21 deaths; 398 cases of diphtheria, with 51 deaths; 321 cases of scarlet fever, with 18 deaths; 2 cases of smallpox; 86 cases of varicella; 407 cases of tuberculosis, and 170 deaths; 34 cases of typhoid fever, with 6 deaths and 63 deaths from cerebrospinal meningitis.

New York and Brooklyn Graduates.—President Schurman of Cornell University conferred degrees on a class of 55, June 8, and the doctorate address was delivered by Dr. William W. Keen, Philadelphia.——A class of 47 was graduated by the Long Island College Hospital, Brooklyn, June 2. The address was delivered by Rev. L. Mason Clarke, D.D., and the president, Dr. John A. McCorkle conferred the degrees.

The Tuberculous Colony on North Brothers Island.—This camp was established to determine the effect of sea air in the vicinity of New York on tuberculosis when the same mode of life is adopted that is followed in camps in other localities. Dr. Briggs reports that the results are very satisfactory and encouraging. Owing to the bad condition of the patients taken from the streets of New York there is some mortality, but where there had been any basis to work on, the results had exceeded all expectations.

PENNSYLVANIA.

Warrants for Meat Embalmers.—Dr. Warren, dairy and food commissioner, has secured 100 warrants to be issued against local meat dealers, charging them with the sale of chemically treated meats; 15 of the warrants have already been issued Dr. Warren found that the samples examined were preserved with chemicals, the most poisonous of which were sulphites and coal-tar products.

Philadelphia.

Health Report.—There still continues to be marked and progressive decrease in contagious disease. There were 78 new cases of typhoid fever and 16 deaths, as against 102 cases and 19 deaths during the previous week. Only 4 new cases of smallpox were reported. This is the lowest number for many months. The deaths from all causes numbered 426, a decrease of 39 from the previous week, and an increase of 4 over the corresponding period of last year.

Pozzi, Treves and Hoffa in Philadelphia.—Prof. S. Pozzi, the eminent French surgeon and gynecologist, is the guest in this city of Dr. Charles P. Noble, who gave a reception and dinner in his honor June 11, which was largely attended.——Sir Frederick Treves, the eminent English surgeon, arrived in this city June 12, and is the guest of Dr. J. William White. He will sail for home on June 24, accompanied by Dr. White and his family.——Prof. D. Abert Hoffa held his second clinic in the Jefferson Hospital, June 6, for the benefit of members of the American Medical Association en route to Atlantic City.

Dedication of New Medical Laboratories.—The opening and dedication of the new medical laboratories of the University of Pennsylvania were held June 11. The exercises were attended by physicians from all parts of the country, and many prominent European physicians were present. A special train conveyed a large contingent of members of the American Medical Association from Atlantic City. The address of presentation was delivered by J. Vaughan Merrick, member of the board of trustees, and formal addresses were made in the Laboratory of Pathological Histology by Dr. Henry P. Bowditch, professor of physiology, Harvard University; Prof. R. H. Chittenden, director of the Sheffield Scientific School, Yale University; Dr. George Dock, professor of medicine, University of Michigan, and Dr. Horatio C. Wood, professor of materia medica, pharmacy and therapeutics, University of Pennsylvania. In completeness of construction and equipment, the new building is without a rival. The erection of the laboratories has occupied four years, and has cost, exclusive of ground and equipment. $700,000.

GENERAL.

National Association for the Study and Prevention of Tuberculosis.—This body was formally organized at Atlantic City, June 6, with the following officers; President, Dr. E. L. Trudeau, Saranac Lake, N. Y.; Secretary, Dr. E. Jacobs, Baltimore.

American Proctologic Society.—At the annual meeting at Atlantic City the following officers were elected: President, Dr. J. Rawson Pennington, Chicago; vice-president, Dr. Lewis Hadlock, Philadelphia; secretary and treasurer, Dr. A. B. Cook, Nashville, Tenn.

American Medico-Psychological Association.—This association met in St. Louis, May 30 to June 2 and elected officers as follows: Dr. E. A. Burgess, Montreal, Canada, president; Dr. C. B. Burr, Flint, Mich., vice-president; Dr. C. A. Dent, New York, secretary and treasurer. A committee was appointed to formulate rules for expert witnesses in criminal cases in which the question of sanity is raised. San Antonio, Tex., was selected as the meeting place for 1905.

American Climatological Association.—The thirty-eighth annual meeting of this association was held in Philadelphia June 2-4. Over 50 members were present, and the meeting was one of the most successful and interesting in the history of the association. The following officers were elected: President, Dr. W. F. R. Philips, Weather Bureau, Washington, D. C.; vice-presidents, Drs. S. G. Bonney, Denver, and S. D. Risley, Philadelphia; secretary and treasurer, Dr. Guy Hinsdale, Hot Springs, Va.

New Society on Use of Alcohol.—The Association for the Study of Inebriety, and the Medical Temperance Association combined at Atlantic City and formed a new society called the American Society for the Study of Alcohol and Narcotic Drugs. The following officers were elected: Honorary president, Dr. N. S. Davis, Chicago; active president, Dr. W. S. Hall, Chicago; vice-presidents, Dr. S. D. Mason, Brooklyn; Dr. C. H. MacNicholl, New York City; Dr. Frank T. Reese, Courtland, N. Y.; secretary, Dr. T. D. Crothers, Hartford, Conn.; corresponding secretary, Dr. W. T. Steward, Battle Creek, Mich.; treasurer, Dr. G. W. Webster, Chicago. The *Journal of Inebriety* was made the organ of the new society.

Marriages.

George I. Cason, M.D., to Miss Mary Rees, both of Colusa, Cal., May 26.

Walter D. Price, M.D., to Miss Dolores Gill, both of Brooklyn, June 1.

Edwin L. Bebee, M.D., of Buffalo, N. Y., to Miss Emily B. Hastings, June 1.

Charles Lee Nollau, M.D., to Miss Freda Weber, both of Louisville, June 15.

Mactier Warfield, M.D., to Miss Mary Campbell Murdoch, at Baltimore, June 8.

August C. Busch, M.D., Cincinnati, to Miss Bering of Fayetteville, Ohio, June 8.

Eugene R. Lewis, M.D., to Miss Elizabeth Bradley, both of Dubuque, Iowa, June 16.

Jesse Wooton Williams, M.D., to Miss Jane Grey Thrift, both of Baltimore, June 1.

Henry A. Polkinhorn, M.D., to Miss Grace Elizabeth Butler, both of New York, June 1.

S. Denny Wilson, M.D., Easton, Md., to Miss Anna E. Voit, at Tunis Mills, Md., June 1.

William Thomas Williams, M.D., to Miss Ida Lelia, both of Natchitoches, La., June 15.

Albert William Myers, M.D., Milwaukee, to Miss Mary Lukens of Philadelphia, June 8.

Joseph H. Liebkemann, M.D., to Mrs. Minnie M. Ferguson, both of Memphis, Tenn., June 5.

John K. Hooper, M.D., Camden, Maine, to Miss Carrie Luella Forbush of Machias, Maine, May 25.

Greer Hill Baker, M.D., Cincinnati, to Miss Mildred Louise Southgate of Newport, Ky., June 1.

Frederick J. Walter, M.D., Kramer, Ind., to Miss Idelle Kidder of Terre Haute, Ind., June 2.

Harry M. Lamberson, M.D., Connersville, Ind., to Miss Mayme Henry of Columbus, Ind., June 8.

Taber R. Washburn, M.D., Donnellson, Iowa, to Miss Christina H. Hanson of Keokuk, Iowa, June 1.

Arthur E. Threlkeld, M.D., Wheatley, Ky., to Miss Pauline Winston of Idlewood, Ky., June 8.

George T. Honaker, M.D., Hallsville, W. Va., to Miss Josephine Frances Stone of Chicago, May 31.

William Marcy Gratiot, M.D., Mineral Point, Wis., to Miss Emily Edwards Cady of Dubuque, Iowa, June 1.

Clifford Walter Allison, M.D., New York City, to Miss Maud S. Speirs of Mount Vernon, N. Y., June 1.

Jacob J. Kennedy, M.D., Frankford, Mo., to Miss Lola Jacobs of Bowling Green, Mo., at St. Louis, June 1.

Albert Coulson Buckley, M.D., Philadelphia, to Miss Harriet Bailey of Covington, Ky., in Cincinnati, June 1.

Harold Roy Lucas, M.D., Grandin, Mo., to Miss Alberta Bracken of Wallace, Kan., at Kansas City, Mo., May 24.

David R. Moore, M.D., Stanley, N. B., to Mrs. Annie E. Young of Sioux Falls, S. D., at Vanceboro, Maine, May 31.

William Lawson Little, M.D., first lieutenant and assistant surgeon, U. S. Army., to Miss Evelyn Ryall of Chattanooga, Tenn., June 1.

Deaths.

Charles Mann, M.D. Medical College of Ohio, Cincinnati, 1861, a member of the American Medical Association for 40 years, of the Kentucky State Medical Society and of the Jessamine County Medical Society; surgeon in the Confederate service during the Civil War; one of the oldest and most prominent physicians of that section of Kentucky, died at his home in Nicholasville, June 1, from paralysis, after a brief illness, aged 67. The county medical society, at a special meeting, passed resolutions of eulogy and regret.

Joshua C. Noyes, M.D. Rush Medical College, Chicago, 1863, a member of the American Medical Association; surgeon of the Thirty-second Wisconsin Volunteer Infantry in the Civil War; one of the oldest and most respected citizens of Oshkosh, Wis., died at St. Mary's Hospital in that city, June 7, a day after amputation of the right leg near the hip joint for osteosarcoma, aged 64. The Oshkosh Medical Club, at a special meeting, June 8, adopted resolutions of regret.

George M. Stiles, M.D. University of Pennsylvania Medical Department, Philadelphia, 1866, of Conshohocken, Pa., died, June 9, at the University Hospital, Philadelphia, to which he had been removed after being stricken with apoplexy two days before. He was a member of the American Medical Association, the Medical Society of the State of Pennsylvania, the Montgomery County Medical Society, and a trustee of the State Hospital for the Insane, Norristown.

Lawrence G. Andrews, M.D. Cleveland Medical College, 1854, for many years a well-known physician of Youngstown, Ohio; assistant surgeon of the Twenty-fifth Ohio Volunteer Infantry in the Civil War, died at the Western Pennsylvania Hospital for the Insane, Dixmont, where he had been a patient for 20 years, June 1, aged 75.

Elmer A. Johnston, M.D. Rush Medical College, Chicago, 1897, of Danville, Ill., a member of the American Medical Association, and of the Vermilion County Medical Society, died at the home of his parents in Champaign, Ill., June 3, from malignant disease of the face, after an illness of one year, aged 36.

Pohatan Jordan, M.D. University of Pennsylvania, Philadelphia, of Beaumont, Texas; formerly preceptor in anatomy in the University of Georgetown Medical Department; surgeon in the U. S. Army, and during the Civil War in the Confederate Army, died at the Sisters' Hospital, Beaumont, May 31, aged 77.

Myron H. Andrews, M.D. University of Buffalo (N. Y.) Medical Department, 1847. for many years surgeon of the Michigan Central Railroad at Detroit, and city physician from 1888 to 1891, died at his home in Detroit, June 3, from pneumonia, after an illness of four weeks, aged 87.

Frederick L. Henkel, M.D. University of Pennsylvania, Philadelphia, 1879, of Staunton, Va., died at Lebanon Church, near New Market, Va., May 21, from the effects of an overdose of morphin, aged 50. He had been in ill health for eighteen months.

John M. Jackson, M.D. University of Louisville Medical Department, 1859, died at his home in Columbus, Ky., May 31, from Bright's disease, after a lingering illness, aged 76. He served as surgeon in the Confederate Army during the Civil War.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending June 11, 1904:

Phillips, Jno. L., surgeon, reports as in temporary charge of C. S. O., Headquarters Department of the East, Governor's Island, N. Y.

Ford, Clyde S., asst.-surgeon, under orders to report June 13, 1904, at Washington, D. C., for examination for promotion.

Jean, Geo. W., asst.-surgeon, reported for temporary duty at Fort Jay, N. Y., left Fort Adams, R. I., June 2, under Department order.

Woodruff, Charles E., surgeon, granted thirty days' leave, permission to apply for two months' extension on surgeon's certificate of disability.

Torney, Geo. H., deputy surgeon general, avails himself of thirty days' leave of absence.

Dale, Frederick A., asst.-surgeon, granted thirty days' leave of absence.

Reynolds, F. P., asst.-surgeon, relieved from duty at U. S. Army General Hospital, Washington Barracks, D. C., to take effect about July 1, 1904, and ordered to the Presidio of San Francisco for duty.

Harnett, Eugene H., and Mathews, Geo. W., asst.-surgeons, ordered to report at Army Medical Museum, Washington, D. C., at such times as may be required by Major Wm. H. Arthur, surgeon, president examining board, to determine their fitness for advancement.

Watkins, Victor E., contract surgeon, relieved from duty at Fort Miley, Cal., and assigned to duty at Fort Apache, Ariz.

Whitney, Walter, contract surgeon, granted leave of absence for two months from the Philippine Division, with permission to visit the United States, and also to apply for an extension of one month.

McConathy, Herbert M., contract surgeon, granted leave of absence for three months from the Philippine Division, with permission to visit the United States.

Brown, Polk D., contract surgeon, granted leave of absence for three months from the Philippine Division, with permission to visit the United States.

Love, Joseph W., contract surgeon, granted leave of absence for two months from the Philippine Division, with permission to visit the United States and to apply for an extension of one month.

Wilkins, Archibald M., contract surgeon, granted leave of absence for three months from the Philippine Division, with permission to visit the United States.

Chase, Alpha M., contract surgeon, left Fort Reno, Okla., June 3 on leave of absence for three months under Department order.

Many, Harry C., contract surgeon, left Fort Riley, Kan., June 2 on leave of absence for two months under Department order.

Reddy, Joseph W., contract surgeon, is now at his home, Boston, Mass., on leave of absence for two months from the Philippine Division.

Jones, George B., contract surgeon, recently returned from Philippine service, and now at his home, Rushville, Ind., has been granted leave of absence for one month.

Hogue, Gustavus I., contract surgeon, now on leave of absence from the Department of California; has been granted an extension of one month.

Brown, Henry L., contract surgeon, stationed at Columbus Barracks, Ohio, has been granted leave of absence for fourteen days, with permission to apply for an extension of seven days.

Stoney, Randell C., contract surgeon, returned to duty June 8 at Fort Hamilton, N. Y., from leave of absence.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending June 11, 1904:

Guthrie, J. A., P. A. surgeon, detached from the *Franklin*, and granted leave for three months.

Hart, G. G., A. A. surgeon, detached from duty with recruiting party No. 5 and ordered home and to wait orders, from June 4.

Sellers, F. E., A. A. surgeon, ordered to the *Franklin*.

Fauntleroy, A. M., asst.-surgeon, ordered to the *Lancaster* June 22.

Angwin, W. A., asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant, junior grade, from June 2, 1904.

Ross, J. W., medical director, detached from the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to duty with the Isthmian Canal Commission.

Munson, F. M., asst.-surgeon, detached from the naval station, Polloc, P. I., and ordered to the naval station, Olongopo, P. I.

Kite, I. W., surgeon, orders detaching from the *Maine* revoked; ordered to continue duty on the *Maine*.

Smith, C. G., asst.-surgeon, ordered to the Naval Hospital, Mare Island, Cal., June 23.

Abekin, F. G., asst.-surgeon, detached from the naval station, San Francisco, and ordered to the *Adams*.

Nelson, Jr., H. T., A. A. surgeon, detached from the Naval Hospital, Sitka, Alaska, and ordered home and to wait orders.

Miller, J. T., A. A. surgeon, detached from the Naval Hospital, Mare Island, Cal., and ordered to the Naval Hospital, Sitka, Alaska.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended June 10, 1904:

SMALLPOX—UNITED STATES.

California: May 21-28, 4 cases.
Florida: Jacksonville, May 27-June 4, 1 case.
Georgia: Macon, May 28-June 4, 5 cases.
Illinois: May 1-31, Belleville, 9 cases; East Liverpool, 22 cases, 1 death; Chicago, May 28-June 4, 7 cases.
Iowa: Dubuque, May 28-June 4, 1 case, 1 death.
Louisiana: New Orleans, May 28-June 4, 11 cases.
Maine: Machiasport, May 1-31, 8 cases.
Maryland, Baltimore, May 28-June 4, 2 cases, 1 death.
Michigan: May 28-June 4, Detroit, 1 case; Grand Rapids, 1 case; at 101 localities, present.
Nebraska: Omaha, May 21-28, 3 cases.
New Hampshire, Manchester, May 28-June 4, 27 cases.
New York: New York City, May 28-June 4, 2 cases.
Ohio: May 28-June 4, Dayton, 17 cases, 1 death; Toledo, 6 cases.
Pennsylvania: May 28-June 4, Johnstown, 3 cases; Philadelphia, 10 cases, 5 deaths; Pittsburg, 3 cases.
South Carolina; Charleston, May 28-June 4, 2 cases.
Tennessee: May 28-June 4, Memphis, 14 cases; Nashville, 12 cases.
Wisconsin: Milwaukee, May 28-June 4, 7 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, April 16-30, 12 cases, 4 deaths.

SMALLPOX—FOREIGN.

Austria: Prague, May 7-14, 4 cases.
Belgium: Antwerp, May 15-21, 5 cases, 4 deaths.
Brazil: Bahia, April 30-May 7, 4 cases; Rio de Janeiro, April 17-May 8, 167 cases, 98 deaths.
Canada: Winnipeg, May 21-28, 2 cases.
China: Shanghai, April 16-30, 2 cases, 14 deaths.
Colombia: Barranquilla, May 9 16, 2 deaths.
France: Paris, May 14-21, 10 cases, 1 death.
Great Britain: May 14-21, Cardiff, 5 cases, 1 death; Dundee, 1 case; Glasgow, 14 cases, 2 deaths; Leeds, 2 cases; London, 18 cases; Newcastle-on-Tyne, 8 cases; Nottingham, 3 cases, 1 death; Leith, May 7-14, 1 case.
India: Calcutta, April 23-May 7, 11 deaths; Karachi, May 1-9, 10 cases, 4 deaths.
Mexico: City of Mexico, May 22-29, 16 cases, 8 deaths; Torreon, May 23 28, 2 cases, 2 deaths.
Netherlands: Rotterdam, May 14-28, 5 cases.
Russia: Moscow, May 7-14, 5 cases, 1 death; Odessa, May 7-21, 1 case, 2 deaths.
Spain: Barcelona, May 10-20, 9 deaths.
Straits Settlements: Singapore, April 8-16, 1 death.
Turkey: Alexandretta, May 14-21, 1 death; Beirut, April 30-May 14, present; Constantinople, May 15-22, 4 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, April 17-May 8, 11 cases, 8 deaths.
Mexico: Vera Cruz, May 22-28, 1 case, 1 death.

CHOLERA.

India: Calcutta, April 23-May 7, 203 deaths: Madras, April 23-29, 1 death.

PLAGUE—INSULAR.

Philippine Islands: Manila, April 16-30, 8 cases, 8 deaths.

PLAGUE—FOREIGN.

Africa: Cape Colony, April 23-30, 1 case.
Brazil: Rio de Janeiro, April 17-May 8, 4 cases.
China: Amoy, June 4, present.
India: Karachi, April 23-May 8, 203 cases, 176 deaths.

Association News.

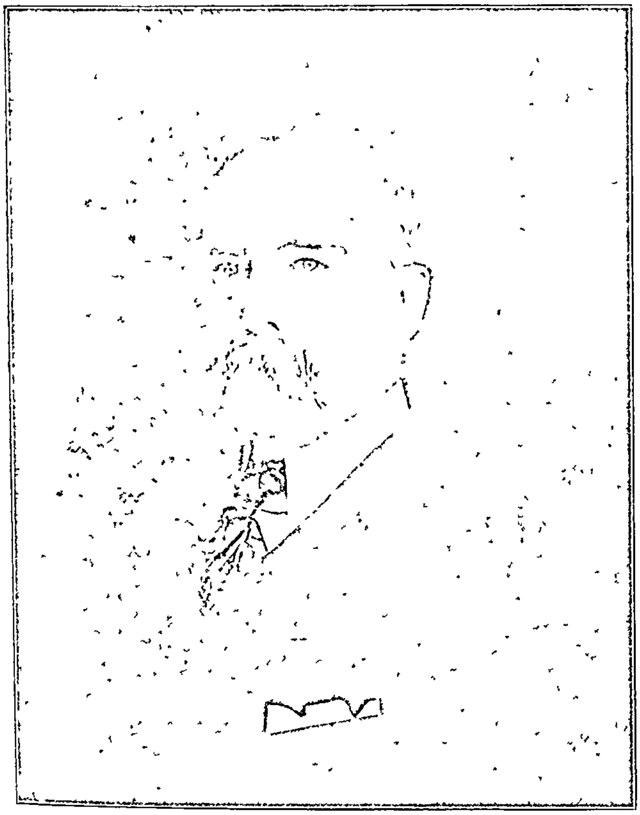
LEWIS S. M'MURTRY.

The President-elect of the Association.

BIOGRAPHICAL SKETCH.

Lewis S. McMurtry, President-elect of the American Medical Association, was born and reared in Central Kentucky, and has lived continuously in his native state. His family were among the early settlers of Kentucky, and came of Scotch ancestry. He is 52 years of age. He was educated at Center College at Danville, where he received the degree of A.B. when 19 years of age; three years later the same institution conferred on him the degree of A.M. in course. After three years pupilage, he was graduated from the medical department of the Tulane University of Louisiana, at New Orleans, and served the year following graduation as one of the chiefs of clinics in the Charity Hospital of that city. Returning to Kentucky, he entered on the practice of medicine at Danville, Ky., where he continued in practice several years. In 1881 he was elected to the chair of anatomy in the Kentucky school of medicine at Louisville, but did not remove to Louisville permanently until several years later. In 1883 and 1884 he pursued special studies in pathologic histology and clinical surgery in New York and Philadelphia, and in 1889 he spent several months in Europe studying especially gynecology and abdominal surgery. In 1889 he removed his residence permanently to Louisville, and has since devoted himself exclusively to the practice of gynecology and abdominal surgery. He has been prominently identified since that time with the advancement of that important department of surgery.

Dr. McMurtry has for ten years past occupied the chair of gynecology and abdominal surgery in the Hospital College of Medicine in Louisville, and is a member of the attending staff of the Louisville City Hospital, surgeon to the Sts. Mary and Elizabeth Hospital, and to the Gray Street Infirmary. He is a member of the American Surgical Association. He was president of the Kentucky State Medical Society in 1889, and was chairman of the committee which erected a monument to the memory of Ephraim McDowell, "the father of ovariotomy." He was president of the Southern Surgical and Gynecological Association in 1891, and of the American Association of Obstetricians in 1893. He has been an active member of the American Medical Association ever since his graduation in medicine, and was a member of the first Board of Trustees, rendering efficient service in founding and establishing The Journal.



Lewis S. McMurtry.

Dr. McMurtry has been a frequent contributor to medical literature. His contributions are to be found mostly in the transactions of the societies with which he is connected, and relate to surgical subjects. He contributed the chapter on the "Surgery of the Uterus" to the "International Text-Book of Surgery," and made numerous contributions to Reed's "Text-Book of Gynecology." He is an honorary member of the Philadelphia Obstetrical Society; an ordinary fellow of the Edinburgh Obstetrical Society, and a fellow of the British Gynecological Society. He is one of the founders of the International Periodical Congress of Gynecology and Obstetrics.

UNVEILING EXERCISES OF THE RUSH MONUMENT.

Held in Washington, D. C., June 11, 1904.

The imposing statue of Dr. Benjamin Rush, perpetuating in bronze the likeness and memory of the great physician and philanthropist, was unveiled Saturday, June 11, 1904, at 5 p. m., in the presence of the President of the United States, members of his cabinet, prominent officers of the Army and Navy, and members of the American Medical Association and the profession generally.

Description of the Monument.

The statue is of heroic size and stands in the grounds of the United States Naval Museum of Hygiene and Medical School, at the foot of Twenty-third Street, N. W., formerly the site of the old Naval Observatory. It stands on a base of Indiana limestone, with granite steps leading up thereto. The height of the pedestal is ten feet. There are four bas relief panels on the several sides of the pedestal. The one in front bears the inscription: "Dr. Benjamin Rush, physician and philanthropist, 1745-1813." The three remaining panels typify the important features of the physician's life. One panel bears crossed swords and a wreath, and beneath is inscribed, "Signer of the Declaration of Independence." Another panel bears a scroll, a pen and wreath, with the inscription, "First American Alienist." The remaining panel bears the Caduceus, or staff of Mercury, with asps coiled about it. The Caduceus is the emblem of medicine recognized in the United States Army. This panel bears a favorite quotation by Dr. Rush: "Studium sine calamo somnium." Mr. Louis R. Metcalf was the architect of the statue, Mr. R. H. Perry, the sculptor, and J. W. Pacey, the builder. The bronze work was done by the Henry Bonnard Company of New York.

Address of President Musser.

Dr. John H. Musser, president of the American Medical Association, in opening the exercises, spoke as follows:

In keeping with that spirit which prevails in all nations, and all institutions advanced in thought, possessed of ideals, reverent of ideas, the American Medical Association naturally would wish to perpetuate in bronze those heroes who by word and deed represented their aspirations and feelings. It is not to be wondered at that he whose monument is to be dedicated to-day should have been one of the first selected. Heroic of action, noble of motive, humane in instincts, his career well represents much of the best of our profession. It can not be gainsaid that he was not without blemish; it can not be gainsaid that while motive should not be impugned, certain action must not be condoned. It is all the more a tribute to the transcendant force of the man, that notwithstanding many weaknesses, he stands among the first of the giants of the revolutionary and formative periods of our government. It is a tribute to the breadth of mind and liberality of feeling of the medical profession of the day that shadows are not allowed to blur the picture but rather to project in clearer outline the great elements of his character.

Such catholicity, it may be said, followed, and as surely follows as the night the day, devotion to the rigid morals of science which has characterized our labors the past quarter of a century.

To the end that our desires should be consummated the American Medical Association placed in the hands of a committee, styled the Rush Monument Committee, the methods to be followed. This committee has had many distinguished members, but without invidious distinction, it is due him to say that to Commodore Gihon of the Medical Corps of the Navy we owe more than to any one individual for arousing sentiment and stimulating action. To him we owe that process of education which is requisite in great movements, the resultant force of which will have unbounded sway, as may be illustrated by the ready response of the profession to the Walter Reed Memorial Association.

The committee, therefore, who have had the conservation of this trust in their care the past four years have the great satisfaction of seeing its fruition, not alone in the completion of the monument, but also in the development of a purpose and sentiment which bodes well for future similar action.

Mr. President, ladies and gentlemen, as representative of the American Medical Association, and through it, the medical profession, official sanction is hereby given by these simple services to the dedication of this monument. Stimulated by his thought and deeds, may we so live that for all time we can show by thought and act that in placing this tribute to a scholar, a patriot, a physician in the trust of the nation we are honoring ourselves far more than we can ever honor him.

The Oration by Dr. Wilson.

At the close of President Musser's remarks, Dr. J. C. Wilson was introduced, and delivered the oration on Benjamin Rush. (This appears in The Journal this week, page 1601.)

The statue was unveiled by Mr. Metcalf, amid great applause, the Marine Band playing "My Country 'Tis of Thee."

Address by President Roosevelt.

At the conclusion of the oration by Dr. Wilson, President Musser introduced the President of the United States, who spoke as follows:

Mr. Chairman, Ladies and Gentlemen: I accept on behalf of the nation the gift so fittingly bestowed by one of the great professions, this statue of a man who was eminent, not only in that profession, but eminent in his service to the nation as a whole. We have listened to an interesting study of the life of Benjamin Rush, and it must surely have been brought home to each of us here that his career derives its peculiar significance in part from the greatness of his pioneer work as a physician on this Continent, in part from the way in which he combined with arduous and incessant labor in his profession the greatest devotion even outside of that profession to the welfare of his fellow countrymen. Here at the National Capital it is earnestly to be hoped that we shall finally see commemorated, as the services of Rush are henceforth to be commemorated by this statue, all the great Americans who, working in widely different lines, by the aggregate of their work make the sum of achievement of America in the world. (Applause.)

I thank and congratulate you of the medical profession today on what you have done, not merely in commemorating the foremost pioneer in your own profession, but in adding at the National Capital a figure to the gallery of great Americans who should be here commemorated. (Applause.)

As you said, Doctor, Benjamin Rush was not a specialist in the modern sense. He could not be. There were not any specialists in the modern sense, as you pointed out. There was no possibility of there being such. But I would like, in this age of specialization, to say one word in the way of a short sermon to eminent specialists. To-day no specialist in a Democratic country like ours can afford to be so exclusively a specialist as to forget that one thought of his duty, namely, his duty to the general public and to the State. (Applause.)

Where government is the duty of all, it of course means that it is the duty of each, and the minute that the average man gets to thinking that government is the duty of somebody else, that minute the republic will begin to go down. It is a fortunate thing for our country that we should have before us the lives of men like Rush, who could take a part in our public life as distinguished as is implied by having been a signer of the Declaration of Independence, and yet do it without a particle of neglect of the man's own proper duties. (Applause.)

I would earnestly plead, in addressing this audience, and especially the members of the high and honorable profession which has given this gift to the nation, that you never for one moment allow yourselves to forget that the well-being of the Republic ultimately depends on the way in which, as a rule and habitually, the best citizen of the Republic does his duty to the State (applause); and that we have a right not merely to expect but to demand from our hardest worked men, from the leaders of the great professions, the full performance of that public service, which consists in a zealous, intelligent, and fearless performance of the ordinary duties of public life by the ordinary private citizen. (Applause.)

In conclusion, I thank you for having presented to the National Capital, to the people of the United States, the statue of a man who was foremost as a leader and a pioneer in his profession, who was a great physician and a great American. (Loud applause.)

AMERICAN MEDICAL ASSOCIATION

Proceedings of the Fifty-fifth Annual Session, held at Atlantic City, N. J., June 7-10, 1904.

(Continued from Page 1582.)

OFFICIAL MINUTES—HOUSE OF DELEGATES.

Third Meeting—Tuesday, June 7.

Dr. John B. Roberts of Philadelphia, in the absence of President Musser, was elected temporary chairman.

The House was called to order at 2:15 p. m.

Resolutions on National Incorporation.

Dr. T. J. Happel presented the following resolutions as summarizing the action of the joint committee (see page 1581), which consisted of the Committee on National Legislation, the Reference Committee on Medical Legislation, and the Board of Trustees, with reference to national incorporation:

Resolved, That the Board of Trustees be, and hereby is, instructed to make such changes in the present charter as may become necessary or desirable owing to changes which have been made in the Constitution and By laws; and

Resolved, That the Committee on National Incorporation, together with the Board of Trustees, be, and hereby is, instructed to secure from Congress, if possible, a suitable and desirable national charter.

New Constitution and By-Laws Adopted.

After some discussion action on these resolutions was deferred until after the report of the Reference Committee on Constitution and By-laws, which was read by Dr. M. L. Harris, chairman (see page 1581).

At this juncture President Musser arrived and took the chair.

At the conclusion of the report Dr. J. N. McCormack, Kentucky, moved the adoption of the report of the committee, which was seconded by several.

Dr. J. W. Grosvenor, Buffalo, moved to amend Article IX, Section 1, of the report, by inserting the word "four" instead of "two," so that the section may read "four vice-presidents" instead of "two."

This amendment was accepted by the committee, after which the original motion of Dr. McCormack to adopt the report of the committee as amended, was put and carried.

Plan for National Incorporation Adopted.

After the adoption of the report of the Committee on Constitution and By-laws, Dr. Happel re-read the resolutions in regard to instructions to the Board of Trustees regarding the changes in the present charter and national incorporation, which were adopted.

Dr. John B. Roberts, Philadelphia, offered the following resolution, which was adopted:

Resolved, That the officers and the members of the House of Delegates of the American Medical Association now in session at Atlantic City, do hereby pledge their loyal support and earnest efforts in aid of securing national incorporation of the American Medical Association by a special act of Congress.

Report and Resignation of Treasurer.

Dr. C. S. Bacon, in the absence of the Treasurer, Dr. H. P. Newman, who was unable to present the report in person on account of illness, read the report for him, in which he tendered his resignation.

On motion of Dr. Harold N. Moyer, Illinois, the report was accepted, referred to the Board of Trustees, and a vote of thanks extended to Dr. Newman for his long and faithful service to the Association.

Report of the Board of Trustees.

Dr. T. J. Happel then read the report of the Board of Trustees:

To the Officers, Members and House of Delegates of the American Medical Association:

As required by the Constitution and By-Laws of our Association, we present herewith our annual report. This report we trust will give you a clear insight into the condition of the Association financially, and as the publisher of what we believe to be one of the best medical journals in the world.

Before entering on the latter part of our subject we would present to you succinctly, as a financial résumé, first, Exhibit "A," the "Revenue Account for the Year Ending Dec. 31, 1903," as gotten up by the Audit Company which examined the books and accounts of The Journal and Treasurer's offices; second, Exhibit "B," "Balance Sheet Dec. 31, 1903;" third, Exhibit "C," "Disposition of Surplus for the Year Ending Dec. 31, 1903;" all by the same party; fourth, Exhibit "D," "Treasurer's Report for the Year 1903;" fifth, Exhibit "E," "A Comparative Statement, in Tabulated Form, Assets and Receipts of 1903."

The following is a copy of the Auditor's Report:

The Investor's Audit Company, 733 The Rookery.

Chicago, Feb. 4. 1904.

Dr. M. L. Harris, Resident Trustee of Board of Trustees American Medical Association, Chicago:

Dear Sir: In accordance with your instructions we have examined the books and vouchers of the American Medical Association for the year ending Dec. 31, 1903, and we beg to hand you attached hereto the following statements:

Balance sheet as at Dec. 31, 1903.
Revenue account for the year ending Dec. 31, 1903.
Disposition of surplus for the year ending Dec. 31, 1903.

We have examined, properly approved and receipted vouchers or other evidence covering all cash disbursements during the year, and we have traced all cash received from the records of original entry to the credit of the proper accounts in the ledger. We examined the cash on hand during our visit and verified the cash in bank by means of statements furnished by the bankers. We have also examined City of Chicago four per cent. school bonds of the par value of $14,000.00, in possession of the Treasurer.

The books have been neatly and accurately kept, and the office work generally appeared to be highly efficient, considering the fact that there are periods of extreme pressure on the office staff.

The bookkeeping system was revised during the year on the lines suggested in our report, except that the members' accounts are still kept on cards instead of in a permanent bound register or ledger, as we recommended. Additional precautions taken in recording cash received, however, have done much to obviate the objections that existed last year to using cards for members' accounts.

We shall be glad to give you any further information that you may desire. Yours faithfully,

(Signed.) The Investors' Audit Company.

Buttons	567.75	149.71	418.04

Just at this point we desire to call attention to the fact that your Treasurer's report differs from those of former years from the fact that since March 1, 1903, he has been really the *Treasurer* of the Association, receiving from THE JOURNAL office only the surplus funds of the Association, not collecting the dues as formerly. All dues are now collected in THE JOURNAL office, through the bookkeeper. This change in methods of bookkeeping has resulted in simplifying accounts and has curtailed the expenditures of the Association materially, having completely done away with the necessity of transferring monies from THE JOURNAL office, to be within a few days drawn out again from the Treasurer and used in THE JOURNAL office. Now THE JOURNAL collects all accounts, whether dues, subscriptions or advertisements or whatever else they may be, uses the money in paying all expenses of THE JOURNAL and the Association, and hands over the surplus to the Treasurer. He becomes the custodian of the funds of the Association that are not in active use, and of the invested funds. Reference was made more fully to the matter in the report of 1903 and hence we deem it unnecessary to enter into it *in extenso* here.

ADVERTISING.

The amount actually earned during the year was $88,533.65, being an increase of $12,486.82, or about 16½ per cent. over the preceding year. Table No. 1 shows the actual amount earned during the past five years. We have also included 1898 as a comparison, although under the system of bookkeeping then in vogue it was impossible to do otherwise than give the cash receipts; consequently the amount for 1898 represents the cash receipts, while the columns for the other years show the amount earned.

TABLE 1.

1898.	1899.	1900.
$23.629.71	$44.971.10	$50.230.64
1901.	1902.	1903.
$62.233.36	$76.046.83	$88,533.65

During the past year THE JOURNAL has been more strict regarding accepting advertisements, and a large number of advertisements that are being carried by other medical weeklies have been declared not acceptable to its pages.

Most of them were declared unacceptable for the reason that they were considered secret proprietaries. A few, however, were rejected because they were advertised direct to the laity.

CIRCULATION DEPARTMENT.

The following figures represent the gross issue of THE JOURNAL each week during the year 1903:

	Weekly Edition.	
Jan. 3	25,721	
Jan. 10	26,764	
Jan. 17	26,800	
Jan. 24	26,300	
Jan. 31	26,500	132,085
Feb. 7	26,876

	13,899	14.674	28.573	3,860	219

The figures given below indicate the count of the mailing list Jan. 1, 1904, compared with that of Jan. 1, 1903:

---

[1] The realty account does not correspond exactly with amount set forth in the report of the auditors, but the discrepancy is apparent, not real, being due to carrying certain items to real estate account that are treated differently by the auditors.

	Jan. 1, 1903.	Jan. 1, 1904..
Copies to members	12.553	13,899
Copies to subscribers	12,378	14,674
Copies to advertisers	332	321
Copies to exchanges (domestic)	150	141
Copies to exchanges (foreign)	64	62
Copies to medical colleges and libraries	114	102
Copies to subscription agents	81	88
	25,672	29,287

Indicating an increase for the year 1903 over 1902 of 3,615, being a fraction more than 14 per cent.

The following table indicates what percentage of the total number of physicians in each state are taking The Journal. The table does not include members of the Medical Department of the U. S. Army or of the U. S. Public Health and Marine-Hospital Service. Neither does it include copies sent to advertisers, agents, exchanges and college or hospital reading rooms.

State.	Physicians in State.	Number Receiving Journal.	Approximate per cent.
Alabama	2,106	399	19
Arizona	181	61	34
Arkansas	2.326	309	13
California	3.902	916	24

Kentucky	3.372	638	19
Louisiana	1.432	562	39
Maine	1.235	143	12
Maryland	1,917	591	31
Massachusetts	4.949	944	19
Michigan	4.175	1,368	33
Minnesota	1,891	661	35
Mississippi	1.593	302	19
Missouri	6,062	1,205	20
Montana	331	117	36
Nebraska	1,591	417	26
Nevada	74	31	42
New Hampshire	701	153	22
New Jersey	2,172	567	26
New Mexico	171	69	40
New York	12.208	1,635	14
North Carolina	1,485	249	17
North Dakota	302	147	48
Ohio	8,188	1,787	22
Oklahoma	903	195	22
Oregon	647	219	34
Pennsylvania	9,531	2,216	23
Rhode Island	671	169	25
South Carolina	1,124	191	17
South Dakota	497	166	33
Tennessee	3.428	589	17
Texas	4,826	891	19
Utah	287	101	36
Vermont	707	128	18
Virginia	2,020	405	20
Washington	789	320	41
West Virginia	1.382	278	20
Wisconsin	2,391	897	38
Wyoming	126	42	34

Our subscription receipts (receipts from members being considered elsewhere) have steadily increased each year, as the following table will show:

Subscriptions.		Membership dues.	
1898	$ 6 746.55	1898	33.760.00
1899	12.283.52	1899	38.965.00
1900	23.697.03	1900	46,700.00
1901	33.793.45	1901	51.555.00
1902	41.570 48	1902	59.180.00
1903	52,567.38	1903	63,237.00

In spite of the fact that our subscription account is practically a clearing house for membership, since we are continually urging subscribers to become members, nevertheless, as will be noticed our great increase is through subscribers.

Below is given a table showing the number of subscribers for each year, according to the mailing list, commencing with January, 1899, about the time that the present editor took charge of The Journal:

	Members.	Subscribers.
Jan. 1, 1899	7.997	2,453
Jan. 1, 1900	8.445	4.633
Jan. 1, 1901	9.841	8.339
Jan. 1, 1902	11.107	10.795
Jan. 1, 1903	12.553	12.378
Jan. 1, 1904	13,899	14,674

It will be noticed from the table that, while there has been a slow and steady increase in the number of members, there has been a more rapid increase in the number of subscribers. It will be noticed also that the number of subscribers now exceeds the number of members.

The report presented by the Editor to your Board of Trustees reveals plainly the fact that the increase in membership and subscription list has been the result of labors of soliciting agents working for The Journal. These agents visit the members of the profession and present the claims of The Journal to them personally, and in this way many members and subscribers have been gotten. The attempt to increase the membership list by correspondence with the secretaries of county medical societies proved almost a complete failure. Occasionally one would respond, but as a rule they manifested little or no interest in the matter, even when offered a commission on the result of their work. This is not as it should have been. Every county medical society should be canvassed for subscriptions to The Journal, and it should be the duty of the president and secretary to present its claims on the medical profession at least twice a year to their county medical societies. This should be the great source of increase of membership to the Association.

The work of organization, the result of which is the creation of new societies, makes more physicians *eligible* to membership, but it does not increase the number of those that actually become members until they are personally solicited, and the one who will do this is the one who is paid for it.

The tables already given will show that we have a pretty fair percentage of the physicians of the country. We, therefore, can not expect to make the proportionate progress that we have made in the past. The Journal only appeals to the fairly well educated physician, and, while an increasing proportion of the members of the profession are gradually becoming of a higher standard still the proportionate increase in our circulation can not be expected in the future.

Above we show that there has been an increase of 3,615 in our circulation during the year, but it must not be forgotten that this is the net increase. There have been dropped approximately 3,500 from our subscription list. Between 1,500 and 1,800 were dropped for non-payment of their subscriptions, and between 1,600 and 1,700 canceled their subscriptions for various reasons. Besides this, over 1,000 names were dropped from the membership list. Of these 189 from deaths, 222 no longer eligible, 201 non-payment of dues, 345 resigned (not a few on account of age) and 55 not found. In other words, while we only show a net increase, as above stated, we really added to our membership and subscription list about 8,000 new names.

PROFITS.

Each year in our report we have called attention to the fact that the profits made by The Journal should be kept separate and distinct from the net profits of the Association. Each year the expenses incurred by the Association vary, as is shown by the table given below.

In our annual statement we have shown what The Journal has really earned during the year. Heretofore, owing to the fact that two systems of bookkeeping were in vogue—that of the Treasurer's office and that of The Journal office—it was impossible to more than estimate the true profits. This year, by our more perfected system of bookkeeping, we are able to tell exactly what The Journal has gained. In the auditor's statement, "Revenue Account for the Year," under "General Expense," are the following items:

Organization expense	$5.323.19	
Association expense	6.629.80	
		$11.952.99

This amount is an expense incurred by the Association that has absolutely nothing to do with the expense of The Journal.

Accounting all revenues and expenditures, the Association made a net profit of $40,488.68. This profit includes a net income from rentals of $1,400.34 and interest on Chicago city school bonds of $560.00.

From our revenues during the year the Association proper cost $6,269.80 plus organization $5,323.19. Adding these two items to our net profits and deducting the gains above mentioned will leave a net profit for The Journal of $50,481.33, or as tabulated as follows:

Association Net Profits		$40,488.68
Association expenses	$6,629.80	
Organization expenses	5,323.19	11,952.99
		$52,441.67
Less interest on bonds	$ 560.00	
Net income on houses	1,400.34	1,960.34
Journal profit, 1903		$50,481.33

PAPER STOCK.

The following shows the cost of paper stock used in The Journal for the past four years:

1900.	1901.	1902.	1903.
$25,598.00	$29,835.00	$35.675.06	$43,966.57

The following table gives the total number of copies of The Journal issued each year for the past six years (the various items for 1898 being estimated), total number of pages and amount of paper stock used in reams, pounds and tons:

	Copies.	Pages.	Reams	Paper.	Tons.
1898....	597,282	4,756	3,395	321,525	157
1899....	710,950	5.382	4,832	461,420	230
1900....	907,200	6.087	6,747	607,230	303.5
1901....	1,146,575	6.510	9,052	814.680	407
1902....	1,316.695	6,522	10,230	938.700	469 1/3
1903....	1,487,980	6,348	12,368	1,113,100	556 11/20

This table shows an increase in the amount of paper used during the year 1903 over that of 1902 of 87 tons.

An examination of the mailing list given on page . shows that on Jan. 1 there were sent out 29,287 copies of The Journal as compaared with 25,672 copies on Jan. 1, 1903, a gain as already stated of more than 14 per cent. While this gain is gratifying, it is not what it should be. We need and must have a bona fide list of 100,000 readers of and subscribers to The Journal of our Association. No member of the Association should feel that he has done his duty toward it who has not been instrumental in securing a subscriber to our organ. There should be a rivalry between the state organizations in securing this increase. The Association might evolve some scheme to bring about this result.

During the past year we have paid for machinery, including two double flat-bed perfecting presses, $17,391.00.

PRESS ROOM.

In your press room you have:

Two double flat-bed perfection presses, 3 single presses, 2 10-H. P. motors, 1 2-H. P. motor, 1 ¼-H. P. motor, 2 automatic feeders, 3 3-H. P. motors, 2 ½-H. P. motors.

BINDERY.

In your bindery you have, among other improvements:

One folding machine, 2-H. P. motor; 1 folding machine, 1-H. P. motor; 1 Sheridan cutter, 2 stitchers and motor for each.

COMPOSING ROOM.

Here you will find:

Four linotype machines and motors, 2 job presses, imposing stones, type cabinets, board cabinets, etc., together with necessary desks, chairs and stools with everything else needed in a first-class 20th century composing room.

OFFICE.

In the office on the second floor: Seven desks, 4 tables, 3 letter files, 4 bookcases, 5 card index files, 7 typewriters and everything else needed, including safes to make a convenient office outfit.

LIBRARY ROOM.

Reference was made in our report for 1903 to this important adjunct to our building. Located on the third floor, easy of access either by elevator or stairway, removed from the noise of the machinery and the hum of business, it furnishes an ideal place for the winter meeting of your Board of Trustees and a most excellent reading room for the visiting members of the profession. In this room will be found an excellent nucleus for a library, the value of which, as shown by your auditor's report, is placed at $1,000.00, which would fall several hundred dollars below the market prices of the books on the shelves, consisting of the latest medical publications sent for review and otherwise to The Journal.

BUILDINGS.

In the report made to you in New Orleans, May, 1903, we stated that, in addition to The Journal building itself, we had bought and paid for three residences fronting Dearborn avenue, all of which property, including the site of The Journal office, cost us $42,646.96.

The trouble with the coal strikes of last winter impressed on us the necessity for an abundance of room in which to store coal for running purposes in a sufficient quantity to tide our work over any such emergency. This fact induced us to purchase two more residences fronting on Indiana Street, and joining the other houses in their rear, reaching through to the alley parallel with Indiana Street. This property was bought for $14,900, and now rents for $100 per month.

The three houses facing Dearborn Avenue rent for $155 per month. If we figure the houses as covering three-fifths of the property (outside of that bought last summer), the following statement can be made: Three-fifths of the original cost ($42,646.96), $25,588.17; gross income for the year $1,675; total expenses, taxes, insurance, sundry commissions, etc., $658.92. leaving a net income on the three houses of $1,016.08, which is practically 4 per cent. on the investment.

As regards the property occupied by The Journal itself, the following statement should be made:

Cost of building	$41,322.90
Improving stockroom and coal shed	1,574.07
Two-fifth of the taxes	143.16
Insurance on building	179.27
Two-fifths cost of property	17,058.79
Total	$60,278.19

If we estimate that our income should be 4 per cent. on the amount invested in this property, then our rent would cost us $2,411.12, or a little over $200 per month. Before making this purchase we were paying $150 per month rent for one floor, where The Journal attempted to carry on its business at No. 61 Market street. Our quarters had become so cramped and crowded from the growth of the business of The Journal, that at the end of our then lease, to have secured sufficient floor space for carrying on our work safely, not economically, would have cost us $5,000 per annum. A glance at the figures already given will show that we are saving more than $2,500 in the question of rent for The Journal office alone.

Now if we take the three items as follows:

Cost of Journal office	$60,278.19
Cost of three dwellings	25,588.17
Cost of two new dwellings	14,900.00
Total amount invested	$100,766.36

Four per cent. (4 per cent.) on this investment is $4,030.64. Our net income from the three dwellings this year has been $1,016.08 and from the two new dwellings for about six months of the year $384.26, making a total of net rents received $1,400.34; rents on Journal office saved, $5,000; aggregate saved and received, $6,400.34, which is practically 6½ per cent. on the property investment, after deducting insurance, taxes, commissions and sundry small items of expenses.

IMPROVEMENTS.

As already intimated in a preceding part of this report, improvements have been made on the property owned by the Association so as to enable us to store a sufficient amount of coal to meet any ordinary emergency and to permit our purchasing a sufficient amount of paper at any time to meet all ordinary demands.

The Board appropriated such a part of $565 as might be needed to paint and further repair the five dwelling houses. We felt that business methods demanded this outlay. With these improvements made the property owned by you will be in good condition. You are now receiving more than $250 per month rentals from your dwelling houses, with a fair prospect for this amount to increase yearly.

OTHER INVESTMENTS.

We reported to you last year that you owned $14,000 in Chicago City School Bonds worth in cash more than $15,000. Since then we have invested $25,000 more in convertible securities drawing an average of 4 per cent. interest per annum, making a total of about $40,000 already provided of the desired $150,000 of reserve fund which this Association should set aside before any change should be made in its fiscal policy.

This fund should not be laid up at the expense of THE JOURNAL—that is, by curtailing it in any way—but by avoiding extravagant, and for the present injudicious, expenditure of money.

THE JOURNAL should be constantly improved. The ideals of the present editor should be attained finally. It should be made a journal in which every practitioner in America, whether he be a specialist working in his laboratory, a college professor in his lecture-room, or the humblest backwoods physician in in a country district, can find interesting and profitable reading. It should be made a desired and welcome visitor in every physician's office or home in our land.

The fact that more than $8,000 worth of advertising matter was refused during the year of 1903 goes far toward establishing the fact that THE JOURNAL is not published for revenue.

APPROPRIATIONS.

A bill of $314.75 was paid Dr. C. A. L. Reed, Chairman of Committee on National Legislation.

The Rush Monument Fund appropriation of $500 has not up to this time been called for, though Dr. Holton has been notified that it is ready for him when needed by the committee.*

ACCOUNTS, ETC.

We would report that accounts to the amount of $132 were paid the Secretaries of Sections last year, that for the current year "a sum not to exceed $50 was appropriated to cover services, postage and expenses of the Secretary of each Section of the Association." In order that these accounts be promptly met they must be presented to some member of the Board by the third day of the session at Atlantic City. If handed in after that time they can not be properly audited and will be carried over to the February meeting of the Board in Chicago.

We desire again to call attention to the fact that where no specific appropriation has been made for any purpose no money can be paid out. Wherever the House of Delegates desires money to be expended we would suggest that a definit limit be fixed to the appropriation, as has been done with the Committee on Organization and the Scientific Exhibit.

In regard to the control of exhibits of drugs, etc., at our annual session, your Board has not yet been able to formulate any definite course of management better than that of the local committee for this year. We recognize the fact that present arrangements are not entirely satisfactory, but for the Association to assume control of the matter through one of its own officers would be too great a financial venture for the present, and then, too, it would be depriving the local committee of its chief source of revenue out of which to meet the expenses which it incurs, and the obligations assumed by it, and would no doubt decrease greatly the number of local entertainments given to the visiting members. We hope at some future time to be able to suggest some feasible solution of this important question.

We are earnestly insisting that no exhibit should be permitted at any of our meetings, an advertisement of which would not be admitted to the pages of our journal. If the local committee will adhere to this closely, no great harm can be done by leaving this matter in their hands for the present. When the Association shall have secured a large reserve fund to meet emergencies, then it can test the matter fully by undertaking the control of the exhibit hall through a special officer appointed for that purpose. If the Association should do this, it must assume all financial obligations of all kinds connected with each annual session and furnish the funds needed by the local committee to supply many of the social amenities connected with such occasions.

NATIONAL INCORPORATION.

This question has been before your Board both individually and collectively during the past year. Inasmuch as a special committee was appointed by the President of the Association to consider and report on this matter further, we feel that it does not belong to us as a Board to attempt to enter on any discussion of the subject.

ORGANIZATION.

In February, 1903, feeling the urgent need of actively pressing to an early completion the work of reorganization of the state societies along the uniform line adopted by the American Medical Association, Dr. J. N. McCormack was placed in the field as a National Organizer, as reported at the May meeting at New Orleans in that year. It was decided at that meeting, at a conference of the Board with Dr. McCormack, to retain his services in the field for another year. The result of the year's work is known to most of you who have read THE JOURNAL and kept in touch with his work.

Nearly every state has accepted the plan of reorganization proposed, and all are in good faith complying with every requirement of our constitution and by-laws adopted at St. Paul in 1901 and readopted at Saratoga in 1902. So completely has this work been done that we feel safe in dispensing with any further work on the part of our Organizer, and leaving the work in the hands of the several state associations to complete, by organizing a county society in every county in each state and territory in the Union.

The work done by Dr. McCormack has been of inestimable value to the American Medical Association, and was reluctantly undertaken by him. The thanks of the entire Association are due and should be tendered him for the successful completion of his stupendous task. It was a work that demanded a knowledge of men and measures; a knowledge of when to press a matter and when not; of how to present a plan in such a way that it could be grasped and understood by the physician from the city, the mountain and the valley—the city professor and the private practitioner from the country district. We feel that we were especially fortunate in having been able to place Dr. McCormack in this field of labor, that he has carried to a favorable termination a work that could have been managed as well by very few other members of the medical profession.

IN CONCLUSION.

We have presented to you this report of our stewardship; we trust that it has been done in such a way as to be readily comprehended by every member of the Association.

The thanks of the Board are due to our worthy Editor, Dr. George H. Simmons, for the untiring zeal displayed by him in looking after the affairs of THE JOURNAL. It has been largely through him that we are able to present you the favorable exhibit herewith submitted. Respectfully,

E. E. MONTGOMERY, Secretary,
M. L. HARRIS,
W. W. GRANT,
H. L. E. JOHNSON,
WM. H. WELCH,
A. L. WRIGHT,
MILES F. PORTER, Vice Chmn.
T. J. HAPPEL, Chairman.
JOHN F. FULTON.

On motion of Dr. Holton, the report was accepted and referred to the Reference Committee on Reports of Officers.

Reports of President and Secretary Approved.

In the absence of Dr. W. N. Wishard, chairman of the Reference Committee on Reports of Officers, Dr. Edwin Walker was requested by the chairman to say that the committee had examined the reports of the President and the Secretary, and recommended their approval.

On motion, the report of the committee was concurred in.

Report on Branch Associations.

Dr. J. N. McCormack read the report of the Committee on Organization relative to branch associations (printed on page (1580), which was referred to the Committee on Miscellaneous Business (page 1640).

Report on Time of Meeting of State Associations.

Dr. McCormack also presented a report of the committee with regard to recommendations as to time of meeting of State Associations (printed on page 1579), which was likewise referred to the Committee on Miscellaneous Business (page 1640).

---

* This has been paid since the above was written.

On motion, the House adjourned until 9 a. m. Wednesday, June 8.

Fourth Meeting—Wednesday, June 8.

The House convened at 9 a. m. and was called to order by President Musser.

The minutes of the previous meeting were read and approved.

Report of Committee on Rush Monument Fund.

The President called for the report of the Committee on Rush Monument Fund, Dr. James C. Wilson, chairman.

Dr. Henry D. Holton stated that he had made his report as treasurer of the fund, which showed a certain amount of cash on hand. There were bills incurred with reference to the forthcoming dedicatory exercises, so that whatever money was left after these exercises would be returned to the secretary of the committee, and that the report of the committee would be made next year. The committee simply desired to report progress at this time (page 1643).

Report of Medicine and Food Bureau Again Referred.

Dr. J. N. McCormack said that the Reference Committee on Medical Legislation had considered the report of the Committee on National Bureau of Medicines and Foods, which was referred to it (page 1579), and the committee requests that the report be referred to the Enlarged Committee on National Legislation; and on motion of Dr. W. T. Bishop it was so referred (page 1644). The report is as follows:

REPORT OF THE COMMITTEE ON NATIONAL BUREAU OF MEDICINES AND FOODS.

To the President and Delegates:—Your committee herewith reports, as instructed, on the desirability and practicability of establishing a Bureau of Medicines and Foods. The objects contemplated by the bureau are as follows:

1—To relieve physicians, pharmacists and the public of all doubt as to the composition or standards of identity, purity, quality and strength, of such drugs, medicines and foodstuffs as may be submitted to and be found acceptable by a competent board of ten experts, to be chosen as set forth in the public plan accompanying this report.

2—To furnish the physicians and pharmacists, and others who may be interested, with accurate and reliable information concerning articles submitted to the bureau for its supervision.

3—To certify to the standards of identity, purity, quality and strength of such articles as may be determined to be worthy by the board of experts, and of no others.

4—To relieve the physicians, in the manner outlined, of the doubt and uncertainty as to the nature, composition or reliability of the medicines which they are requested by representatives of various houses to prescribe or employ.

Desirability.—There has been no dissenting opinion as to the great desirability of securing the foregoing objects, and of thus improving the quality of medicines and foodstuffs.

U. S. Government Mark.—Your committee was instructed to work with a similar committee of the American Pharmaceutical Association, and also to refer the matters proposed to the proper U. S. Government authorities. In accordance with such instructions the whole question was laid before the Chief of the Bureau of Chemistry of the Department of Agriculture, Dr. Wiley, and a copy of his opinion, in every particular favorable, is herewith filed.

American Pharmaceutical Association Committee.—The work of investigation and consideration has been done by means of correspondence and circular letters, in which every member of the American Pharmaceutical Association committee, and all but one member of our own committee, has participated. A ballot has recently been taken. On the following fundamental points the American Pharmaceutical Association committee's vote was unanimous; ballots have been returned by three out of five members of our committee, and a fourth member has verbally communicated his views. The fundamental questions on which eight of the ten votes are recorded in the affirmative are as follows:

1—There is no apparent hope that the United States Government will provide for the work contemplated.

2—The two national associations are the bodies best constituted to select the board of experts to control such an organization.

3—*The work should be done by certifying to the standard of identity, purity, quality and strength of acceptable articles, such certificates to be attached to original packages of articles known to comply with standards agreed on by the bureau and the Department of Agriculture or other U. S. Government departments having such work in charge.*

4—Condemnation of bad products should not be obligatory, but may, if agreed to by the board of directors, be undertaken.

The plan recommended involves the formation of a bureau as a membership corporation (not for profit) and all members of these associations and other kindred scientific societies may be members of the same. (Copy herewith filed.)

It asks of the associations only one thing, namely, that the associations shall nominate the proper persons to act as directors of the bureau organization.

Responsibility.—Neither association could or would be involved in the slightest financial or legal responsibility, for the bureau would be a separate and corporate entity, shouldering its own responsibilities. On this question of responsibility, several legal firms have been consulted. They all agree that no responsibility can attach to either association for the acts of such a separate corporation as the bureau would be. Copy of one such opinion is filed herewith.

Practicability.—Whether or not the plan can be made successful can only be determined by actual trial. During the past year several firms have changed from opposition to the proposed organization to expressed approval and hope that it may be undertaken.

Your committee recommends that it be enlarged to include one representative from each body having representation in this house, to be appointed by the President; that this enlarged committee consider all the matters presented in this report and accompanying papers, and report thereon and on the advisability of adopting the following resolutions before the close of the present session:

1. *Resolved,* That a committee of five members of this Association shall be appointed who, acting with a similar committee of the American Pharmaceutical Association, may proceed to organize and incorporate the National Bureau of Medicines and Foods as and within the limitations set forth in this report and accompanying papers, and agreed to by the committee.

2. *Resolved,* That this committee may act as temporary directors of such membership corporation.

3. *Resolved,* That at the meeting of this Association following such organization, persons to act as permanent directors in accordance with the membership corporations act of the State of New York shall be elected.

Amended Report of Committee on Organization Held Over One Year.

Dr. Edwin Walker, Indiana, read the report of the Committee on Miscellaneous Business on the report of the Committee on Organization (pages 1579 and 1639).

THE REPORT OF THE COMMITTEE ON MISCELLANEOUS BUSINESS ON THE REPORT OF THE COMMITTEE ON ORGANIZATION.

The report of the Committee on Organization has been carefully considered and with the following amendments is approved:

Relative to the names of the branch associations and the states to compose them we recommend as follows:

1—The North Atlantic Branch ("the New England and," being omitted), the states remaining the same.

2—South Atlantic Branch ("Middle and," being omitted), states remaining the same.

3—Gulf Branch ("Southern and," being omitted), Florida is added and Tennessee dropped.

4—Mississippi Valley Branch ("and Lake," being omitted), Tennessee added to the list of states.

5—Northwestern Branch (Iowa added to the states).

6—Southwestern Branch (Utah added to the states).

7—Pacific Branch (omit "Mountain and").

The complete constitution and by-laws for the district branches was not submitted to this committee and they cannot act on the same.

The recommendation in the report, viz.: "The presidents of the respective state associations become vice-presidents of the branch associations, and the presidents of these larger bodies in turn become the vice-presidents of this Association," is not concurred in, as it involves an amendment to the Constitution and By-laws.

With these amendments this committee recommends the adoption of the report.

The "recommendations as to the time of meeting of state associations," as reported by the Committee on Organization, is approved and its adoption recommended.

Dr. George M. Kober moved the adoption of the report and the recommendation contained therein. Seconded.

Dr. Harold N. Moyer, Illinois, moved as an amendment that the Committee on Organization be continued, and that the report be referred to it to report a year from now. The amendment was seconded and accepted.

The original motion as amended was carried, and the committee instructed to secure an expression from each state medical society in the meantime (modified, page 1645).

Report of Committee on Hygiene Adopted.

Dr. J. N. Hurty, Indiana, chairman, read the report of the Reference Committee on Hygiene and Public Health.

The committee respectfully recommended the adoption of the report referred to it (page 1582) relative to vital statistics, and also that the bill of Dr. Wilbur for printing be allowed.

On motion the report was adopted, and that part pertaining to expenditure of money referred to the Board of Trustees.

Report of Reference Committee on Sections.

Permanent Committee on Sections Proposed.—Dr. A. P. Ohlmacher submitted the following resolution in connection with his report as chairman of the Committee on Sections and Section Work:

Resolved, That the House of Delegates adopt a standing resolution that the President appoint a Permanent Committee on Sections and Section Work, consisting of three members.

It was moved that the resolution be adopted as presented by the committee. Seconded.

Dr. H. S. McConnel, Pennsylvania, raised the point as to whether the President could legally appoint a permanent committee.

After some discussion Dr. A. R. Craig, Pennsylvania, moved that the resolution be referred to the Committee on Constitution and By-laws, which was seconded, and the resolution was so referred, the committee being instructed to report to the House to-morrow morning (page 1644).

Report of Committee on Prophylaxis of Venereal Diseases.

Dr. Henry D. Holton then read the report of the Committee on Prophylaxis of Venereal Diseases, which, on motion of Dr. Craig, was referred to the Committee on Hygiene and Sanitary Science, and that committee was instructed to confer with the Board of Trustees and report to-morrow morning to the House of Delegates (page 1645).

REPORT OF THE COMMITTEE ON PROPHYLAXIS OF VENEREAL DISEASES.

To the House of Delegates:

The Committee on Prophylaxis of Venereal Diseases herewith submits its second annual report for your kind consideration. Believing that venereal diseases are paramount in their consequence and ravages to those wrought by tuberculosis and alcoholism, without, however, receiving the same consideration and popular attention, this committee considers it as one of its main duties to draw the attention of the medical profession, and incidentally that of the public, to the deleterious influence venereal diseases exert on the social, moral and racial conditions of the people. The triad of scourges—tuberculosis, alcoholism and venereal diseases—feeds on the body of our people and permeates all its classes beyond conception. Our legislators have tried to minimize the ravages of tuberculosis by making it reportable to the Boards of Health, which in turn effectually combat its propagation. Prohibition and high-tax license endeavor to curb the alcoholic demon.

Only venereal diseases have not as yet merited the attention either of our legislators or the public in general. This committee has tried to penetrate into untrodden paths and endeavored to hew its way through the primeval forest of prudishness, hypocrisy, secretiveness, false shame and prejudice, into a clearance of very promising features. We have found to our great satisfaction that not only is the medical profession as a unit convinced of the necessity that hygienic measures are imperative to combat venereal diseases, but also government, state, county and municipal boards and officers, university regents, lawyers, artisans, philanthropists and the educated public, each and all, are imbued with endeavor and goodwill to check the alarming spread of venereal diseases. However, it is the general public, the masses, which are dolefully ignorant, indolent, and unwittingly but criminally careless, that must be reached, educated and enlightened, as to the importance, dangers of acquiring, and of the dire consequences of disseminating venereal diseases.

Unfortunately, we are lacking in the most primitive elements of socio-moral legislation, and sanitary and hygienic regulations pertaining to venereal diseases. By a perverse mental process of reasoning, venereal diseases have been put on the proscription list. By sacrificing the effect—venereal diseases—to the regrettable cause—prostitution—those diseases are either tacitly left unnoticed, or if timidly noticed at all, their importance is underestimated. It seems that in endeavoring to appear above suspicion, of even countenancing the unholy outgrowth of socio moral degradation, that most philanthropists, legislators and officials lend their Simon-pure activity to other exigencies, which leaves their endangered virtue and moral integrity above question. We, of the medical profession, can not but regret this deplorable demonstration of hyper-puritanism. We, who come in contact with the dire results of venereal disease in the guilty as well as in the innocent, and see the ravages of it in the trusting wife and innocent offspring, tainted maimed and diseased, with vitiated blood coursing through their veins, a menace to their surroundings and to their race—we can not understand why a Mecenas has not yet arisen to save innocents by founding large hospitals and inhibit the deterioration of the race, which is sure to follow. Where is the hero for such a fund!

It is therefore incumbent on the medical profession to disseminate knowledge on venereal diseases and their prevention. It is the belief of this committee that only a concerted action emanating from our ranks and creating a popular movement by arousing the masses will be effectual. The unselfishness of such a movement, originated by the profession against its own material interests, will at once assure the populace of the high ethical standard of the crusade of education.

The symposium arranged by this committee is only the first step toward succeeding ones, which will take palpable form when this honorable House of Delegates will lend, as it is hoped, its authoritative and material aid for carrying on further investigation.

In our last year's report for the committee, we cited statistical data, illustrating the ravages of venereal diseases on the earning and producing capacity and the well-being of the people. A few new facts gathered since will forcibly bear this out. Both sexes contribute, although not equally so, to the sterility through ascending gonorrheal infection. In men, stricture may mechanically hinder the *potentia generandi,* fibrous cavernitis and suppurative folliculitis, the *potentia coeundi,* gonorrheal involvement of the prostate, which happens in ninety per cent. of gonorrheas, impairs the leavening property of its secretion on the semen, while the gonorrheal infection of the seminal glands makes this receptacle an ill-fit storage place for semen, produced even by healthy testicles.

Sclerosing epididymitis and obliterative funiculitis as a result of gonorrhea, however, are the main causes of sterility in men. Finger has found in 3.136 cases of epididymites gonorrhoica, 211 times to be double-sided; and in 242 cases of double-sided epididymites, azoospermia to occur, in 207 cases. Lier and Asher found it in seventy-five cases without exception. Kehrer found that in ninety-six sterile marriages, 30 per cent. were due to azoospermia after gonorrhea, and Lier and Asher's investigations gave ninety cases of azoospermia in 132 sterile marriages, i. e., 66 per cent., which is about the average percentage of men's share in sterile marriages and of the most frequent sequela of gonorrhea. As about 80 per cent. of all men had contracted gonorrhea and probably 50 per cent. assume a latent form, E. Schwartz has calculated that in large cities, out of 100 married men, 10 enter wedlock afflicted with chronic, yet infectious gonorrhea; and that ten more acquire acute gonorrhea during married life. The source of these gonorrheal infections is traceable in about seventy per cent. to prostitutes.

While gonorrheal infection in men rarely assumes life-endangering properties, in women it will constitute a serious, often dangerous ailment by affecting the uterus and the adnexa, causing painful invalidism and sterility.

Gonorrhea in women will, according to Schenk, cause sterility in approximately 43 per cent. of marriages. In 100 marriages, Jaquet found sterility caused in 61 per cent. by gonorrhea; in 25 per cent. the husband was the direct cause of sterility and in 14 cases stenosis of the os uteri was present. Lier and Asher calculated in cases where both parties were examined that the husband contributed 59.1 and the wife 40.9 per cent. to the sterile condition. This tallies with another investigation, where out of 287 primarily sterile marriages in which the women alone were examined, gonorrhea was found 107 times, i. e., in 34.8 per cent. The approximate main average of the share in which both parties contribute to the existing sterility will be like 33 1/3 to 66 2/3 per cent. This means that out of a hundred sterile marriages, azoospermia of the men will be the cause in one-third and endometritis, pyosalpinx, etc., in two-thirds of the cases. The gonorrheal origin of female generative troubles in general can approximately be estimated, according to Chrobak, at 25 per cent.

It will be necessary in future investigations on sterility always to examine both parties. Tact and discretion in this delicate matter must be presupposed by the physician. This will elucidate much more impressively than was the case hitherto, the deleterious consequences of gonorrheal infection to women and the socio-economic importance for the individual, society and state.

What is the present status of venereal diseases in this country? What is the attitude of different states toward it? The first question can not be decided, inasmuch as each state has its sovereign and independent government and is at liberty to settle this question as it may deem proper. This being the case, each state had to be looked up separately. In order to accomplish this there was assigned to each member of the committee a section of the United States, so that every state and territory was covered. Up to the time of completion of last year's report, twenty states had responded, which were duly mentioned there. When this report goes to press, thirteen more states will have been heard from.

The following were the questions asked:

1—What laws exist in the different states relating to prostitution?

2—Is there a sanitary marriage law which provides for medical examination of the contracting parties?

3—Is there any law against wilfully or knowingly communicating venereal diseases?

4—What, if any, municipal regulations exist in any city of your state regarding these diseases?

5—Is notification required of these diseases in your state?

The following is a summary of the returns from the states which have responded, viz.: Arizona, Connecticut, California, District of Columbia, Idaho, Illinois, Iowa, Kansas, Maine, Maryland, Massachusetts, Michigan, Minnesota, Montana, New Hampshire, North Carolina, Nebraska, Nevada, New York, Ohio, Oregon, Pennsylvania, Rhode Island, South Dakota, Utah, Virginia, West Virginia, Washington, Wisconsin, Wyoming and Vermont.

These 33 states, with the exception of Rhode Island and Connecticut, state in answer to question 1, that they have the usual common laws and sundry police regulations of general character against houses of ill fame, including specified nuisances therein against soliciting in streets, and against enticing of females under 16 years. To questions 2, 3, 4 and 5 the answer in all instances, as far as relating to venereal diseases, is negative, with the exception of Michigan, which is the only state in the Union that has done pioneer work relating to the spread of venereal diseases. It is of sufficient interest to quote it in part:

"No insane person, idiot, or person who has beeen afflicted with syphilis or gonorrhea and has not been cured of the same, shall be capable of contracting marriage. . . . Any person who has been afflicted with syphilis or gonorrhea and has not been cured of the same, who shall marry . . . shall be punished by a fine of not less than five hundred dollars or more than one thousand dollars . . . *Provided,* That in all prosecutions under this act a husband shall be examined as a witness against his wife and a wife shall be examined as a witness against her husband, whether such husband or wife consent or not: And further provided, that in all cases arising under this act any physician who has attended or prescribed for any husband or wife for either of the instances above mentioned shall be compelled to testify to any facts found by him from such attendance. Act No. 247, Laws of 1899. Approved June 15, 1899."

In the legislature of North Dakota a bill was proposed in 1899, but as far as known not acted on; yet, which provides that every candidate for marriage, in order to obtain a marriage license, is held to produce a certificate as to his physical and mental fitness to marry.

It is evident from the foregoing that, (*a*) prostitution is absolutely ignored; (*b*) that there are no laws on the statute books against spreading venereal diseases; (*c*) that venereal diseases are not among the reportable ones; (*d*) that with the exception of Michigan and North Dakota, the other states are not taking any cognizance of the question at all. Being aware that the decentralization in this country is one of the mainstays of our Constitution, and that home rule is carried and coveted to the limit, it soon became evident that some municipalities deal with this question quite independently from their state, possessing local laws and ordinances relating to the social evil.

It was instructive and interesting to ascertain these divergencies and the ways the different municipalities deal with the social evil. To this end, a circular comprising questions akin to the above, was sent with the additional ones about the number of beds and hospital accommodations, which were recorded in the previous reports received since, to forty of the largest cities in the Union. The returns have conclusively shown that—with the exception of Detroit and Cincinnati, which have a reglementation somewhat after continental plans—there are no provisions at all in existence beside the police regulations of general character. These are confessedly not enforced unless some exceptional occurrence of badgering stirs the latent energies of the authorities into a crusade of high moral tension of very ephemeral character.

Not strictly relevant, but of interest in this connection, is an ordinance of the city of Denver, which provides that in the discretion of the health commissioner he may order an examination of a suspected prostitute, and if found diseased, she may be detained in a hospital until the contagious period of her ailment is passed. Los Angeles, Cal., has a large hospital, "which well affords"—the return says,—"ample accommodations for venereal diseases."

In contrast with this munificent provision are the meager accommodations of Buffalo, N. Y., where the old Erie County Hospital for venereal diseases treats about one dozen cases a year! New York, the Empire City, of which we all have reason to be proud for its great charitable and humanitarian institutions, has for the reception and treatment of venereal women just 26 beds and for venereal men 56 beds in the city hospitals at Blackwell's Island.

To sum up, the returns apprise us of the dire fact that not one city has even approximately hospital facilities in proportion to the population. Each city falls far below the average of minimum requirements; a perfect dearth of hospitals.

Beside these attempts of official recognition of venereal diseases, there are also encouraging evidences from the ranks of the medical profession that the endeavors of this committee have struck sympathetic cords. That the profession is conscious of the great social danger which threatens society from the unchecked spreading of venereal diseases is evidenced by the activity of the different medical societies in dealing with this long-neglected question. In the last report of this committee, we had the pleasure to mention that the State Medical Association of Maine had a committee appointed to study the expediency of adding syphilis and venereal diseases to those required to be reported to the Board of Health. It had instructed its delegates to vote in favor of a Congress for Venereal Diseases. The Missouri Valley Medical Association endorsed this progressive movement of the A. M. A. by appointing a committee of three to co-operate with this committee. The State and Provincial Boards of Health of North America have adopted the idea to make venereal diseases reportable. The secretary of the State Board of Iowa: the Board of Health of the City of New York; the chancellors of the University of Nebraska, and the Washington University of St. Louis have expressed their sympathy and co-operation. Numerous state and city officials have worked in the same friendly spirit, expecting action to be taken by the American Medical Association through this committee.

The committee has the pleasure to report two recent additions to our fast-growing numbers of sympathizers. The New Haven County Public Health Association has drafted a resolution requesting the Connecticut State Medical Association to bring about legislation in respect of checking the spread of venereal diseases: recommending co-operation with our committee. The Washington State Medical Society, on Sept. 4, 1903, recognizing the seriousness of venereal diseases and the need of concentrated action, has endorsed such steps as the Committee for the Prophylaxis of Venereal Diseases of the American Medical Association may take in the work and had appointed a committee of three to co-operate with this committee.

It is my pleasant duty to express the thanks of our committee to Dr. G. S. Peterkin, of Seattle, Wash., to whose untiring efforts and strenuous devotion to the cause are due the acquisition of welcome alliance from the far west. He and his associates, by disseminating pamphlets broadcast, have succeeded in arousing the interest of the profession in the western states. We confidently expect that at an early date the State Medical Societies of Oregon, California and Idaho will join the movement inaugurated by the American Medical Association.

Beside this formidable array of co-operators, your committee has received numerous expressions of sympathy for the cause from philanthropists and good advice from the ranks of the profession, to all of whom cordial thanks are expressed.

It will be of interest to note the ways and means continental countries deal with prostitution and venereal diseases. With the exception of England, where the state absolutely ignores—except the army and navy—the existence of venereal diseases, every country there has dealt in some shape or form with the vexatious condition.

To Belgium belongs the honor of having taken the initial step toward an international understanding, which resulted in the formation, in 1899, of the "First International Conference for the Prophylaxis of Venereal Diseases," in Brussels; followed by a second one in 1902. The creation of an international society—"Le Société Internationale de Prophylaxie Sanitaire et Morale"—was the outcome of these conferences.

Soon France, which has a century of unsuccessful experience with reglementation, established its own society, under the name. "Société Francaise de Prophylaxie Sanitaire et Morale," of which Fournier is the leading spirit. France has appointed an extra parliamentary commission to report on the advisability of retaining reglementation.

Through the agitation of Neisser, Lesser, Blaschko and others, Germany soon followed suit by founding the "Deutsche Gesellschaft für Bekämpfung der Geschlechtskrankheiten" (German Society for Combating Venereal Diseases), which had its first meeting Oct. 15, 1902, starting with an enrolled list of 600 members and numbering at present already over 3,500. Members of the royal family, men of letters and art, professionals, government officials and judges, men and women of every walk of society, have joined to combat the spread of venereal diseases, and within the two years of its existence this society has established branch societies through the German empire, publishes its transactions for distribution, and has established a bi-monthly journal (Zeitschrift fur Bekämpfung der Geschlechtskrankheiten). It has held under its auspices at Frankfort-on-Main, in March, 1903, the first congress for combating venereal diseases, and in Berlin, 1904, a second one. Besides these formidable activities, it has edited and distributed half a million leaflets (Merkblatt), containing popular instruction for the prevention of venereal diseases. It has influenced legislation throughout the empire pertaining towards prevention of venereal diseases. It was instrumental in compelling sick-benefit societies to pay diseased venereal members their weekly benefit, from which they were formerly enjoined. It has caused legislation for reporting venereal diseases, especially in prostitutes, and it has petitioned that the provident educational law, which puts unchaste minors, or those endangered by their surroundings, up to their 16th year, under responsible guardianship. Such commitment should be extended to the 18th year. The good influence of this beneficent law is manifested by the fact that during the first year of its existence 2,838—36.4 per cent.—of those committed to compulsory guardianship were females; 710—25 per cent.—of these were from 16 to 18 years. Verily, this is an enviable record and worthy to be emulated by other nations.

Italy, after having instituted and again repealed its laws for regulating prostitution, requires at present only syphilis to be reported.

Denmark has issued laws against the spread of venereal diseases as far back as 1874, and by the revised statute of March 1, 1895, has compelled physicians to return, without names, weekly reports of all forms of venereal diseases. A Danish society for combating venereal diseases has been established in December, 1902.

In Norway, where brothels have been abolished since 1888, physicians are compelled to send in monthly reports, also without mentioning names, of all cases of venereal diseases treated by them. A similar society is contemplated there and also in Sweden.

Direct punitive laws against wittingly communicating venereal diseases are in existence in those northern countries of Europe, also in Hungary, where the treatment of diseased prostitutes or outpatients is forbidden and hospital treatment compulsory. Gratuitous treatment to those afflicted with venereal diseases is granted to everyone regardless of means in Sweden, Norway, Denmark, Hungary, Italy and Bosnia (Austria). To Hungary belongs the honor of having the provision on its statute books that the cost accruing from such stay in a hospital should not be recovered, as is the case everywhere, from the place where the patient hails, but from the community where the cure has taken place. A wise law!

The Russian Syphilo-Dermatological Society, in a meeting held at St. Petersburg, Sept. 27, 1903, contemplated the founding, under its auspices, of a Russian society for combating venereal diseases. In a country where entire villages are infested with syphilis, acquired mostly in an extragenital way, and where nine-tenths of cases so infected are through carelessness and inferior culture, such a society will prove a godsend.

The Scientific Club, in Vienna, at a meeting, March 30, 1904, commenced the organization of such a society for Austria. In Holland, Hungary and Italy movements for the establishment of such a society are on foot.

We see from the foregoing that the advent of a crusade against venereal diseases is on and is close at hand in the United States. Tuberculosis has set the pace. We will have to follow the lead. While in 1875, in Germany, out of every 10,000 people 31 died of consumption, from 1893 on this number commenced to diminish and in 1900 only 21 succumbed. Why? Because in 1893 public instruction was begun, and within a few years results have materialized. There is no reason to doubt that the identical results could be obtained with venereal diseases. It is true the topic is an extremely delicate one: but it is not beyond the skill of human action if properly handled. This committee has come to the conclusion that one of the first requisites for disseminating knowledge on venereal diseases is to make it "discussable." The public at large must be convinced that "*naturalia non sunt turpia*", that things pertaining to sexual life may, and should, be ventilated to make its dangers apparent without fear of losing caste.

This committee has confined its studies to the enormous spread of venereal diseases, without deciding on the merits or the demerits of a "regulation" of the social evil. It has come to a conclusion that systematized action emanating from the medical profession. —a dissemination of knowledge to teach the populace the hygiene of sexual life—is the first step to diminish the dire consequence of venereal disease.

As the states can not with impunity ignore venereal diseases and as it is the duty of the state to protect the people from its ravages, there should be instituted through the state societies a propaganda of action looking towards a proper recognition of venereal diseases by the different legislatures and municipalities.

Your committee most respectfully recommends that this great national body of medical men should take the initiative step towards forming an American Society for Combating Venereal Diseases.

Public sentiment is ripe for such a step, and a national society a necessity. To facilitate the organization of such a society, the American Medical Association should appoint its accredited delegates from each state as a committee to organize in their respective states a State Society for Combating Venereal Diseases, with county branches, which should be in touch with the state societies.

That such state societies should send delegates (who hereafter must not necessarily be members of the House of Delegates of the American Medical Association) to the central society, known as the American Society for Combating Venereal Diseases, which should hold its yearly meetings either at the same time and place as the American Medical Association, or at any other convenient time and place. That the State Societies for Combating Venereal Diseases should issue periodicals and pamphlets to disseminate knowledge of venereal diseases, and that THE JOURNAL of the American Medical Association should be the official organ of the national society, known as the American Society for Combating Venereal Diseases.

That the learned professions, philanthropists, etc., should be invited to become members of such national, state or county societies.

That, if it so pleases, this honorable House of Delegates of the American Medical Association should retain this committee for further studies, directing it to act also as a central committee of the American Society for Combating Venereal Diseases and to be in touch with the various state societies to be founded.

It is further proposed that the delegates of the American Medical Association, convened as the House of Delegates of the Fifty-fifth Annual Session, should become founders of the American Society for Combating Venereal Diseases and that they should meet and organize then and there under the auspices of the Committee on Prophylaxis of Venereal Diseases.

Your committee has until now cheerfully defrayed expenses for pursuing its studies. But inasmuch as the scope of its work becomes more extended from year to year, entailing a larger amount of correspondence and clerical service, it respectfully asks the House of Delegates for an appropriation of $200 to enable it to carry on its work unhampered by financial cares.

Within the short two years that this work has been intrusted to the Committee on Prophylaxis of Venereal Diseases of the American Medical Association, we are confronted with a surprising change of attitude concerning the social evil. The great and growing danger from venereal diseases, which permeates unchecked our population in a degree barely conceivable by the casual observer, the inoculation of guilty and innocents alike by a poison more serious and lasting in its consequences than any other contagious disease; the ravages, especially in the later manifestations, which outclass even those brought about by tuberculosis; and the deteriorating influences on the race and the generations yet to come, has finally awakened the profession and society at large from the habitual lethargy into an attempt at active interference. The way is paved; the time is ripe for action. Theoretical reasoning, committee labor, study of pertinent conditions, while desirable, have had their day. A propaganda of action having as its aim to interest the profession and especially to enlighten the broad masses of the importance and dangers of venereal diseases, is the next step in the crusade to attack the hydra which endangers humanity in the present and threatens it in the future.

In the opinion of the committee, the time has arrived for the organization of a National Society for the Study and Prevention of Venereal Diseases, and it is hoped that the American Medical Association will lend the weight of its influence for founding such a society.

Respectfully submitted.

HENRY D. HOLTON, LUDWIG WEISS, GEORGE M. KOBER, W. H. SANDERS, L. DUNCAN BULKLEY, LOUIS E. SCHMIDT, Committee.

Report of the Committee on Scientific Research.

The Secretary, in the absence of the Chairman, Dr. Alfred Stengel, read the following report of the Committee on Scientific Research, which was referred to the Board of Trustees (page 1644).

REPORT OF THE COMMITTEE ON SCIENTIFIC RESEARCH.

Your committee would report that during the year grants have been made to the following: Drs. G. A. Ruediger, John T. Moore, H. E. Wetherill and Leo Loeb.

The report of Dr. Ruediger's work on "The Mechanism of Streptococcus Infection" will be reported to the Section on Pathology and Physiology at the present session. The researches of the other three men are still unfinished, but are sufficiently forward to justify the continuance of the grant. Dr. Moore is studying the question of etiology of relapses in malaria; Dr. Wetherill, the behavior of sweat secretion in fevers and uremia; and Dr. Loeb, the effect of radium on living tissues.

As far as possible, the committee has felt it desirable to extend aid to such workers as required costly materials or were not supported in their work by established institutions. It has further been the policy of the committee to offer grants for work proposed when the proposal was promising.

We believe that the continuance of the work of this committee will be beneficial in the cause of scientific research.

Resolution on Purification of the Mails.

Dr. H. L. E. Johnson, District of Columbia, offered the following resolution, which was referred to the Committee on Medical Legislation (page 1644).

Resolved, That the American Medical Association endorse the action of the Postmaster General in enforcing the statute which prohibits the use of the United States mails for the distribution of obscene advertisements and fraudulent compounds and appliances.

Resolution on Wood Alcohol as a Dangerous Poison.

Dr. Casey A. Wood, Illinois, presented the following from the Section on Ophthalmology, which was referred to the Auxiliary Committee on National Legislation (page 1644):

WHEREAS, The employment as beverages of wood spirit or methyl alcohol and its various preparations is known to have been responsible for numerous deaths and many cases of blindness in this country during the past few years; and

WHEREAS, Even the breathing of confined air charged with the fumes of this form of alcohol has been shown to produce blindness, it is

Resolved, That the House of Delegates of the American Medical Association, recognizing the dangerous character of wood alcohol and liquors containing it, believes that it should be placed on the list of poisons. It accordingly urges the proper federal and state authorities to take the necessary steps to protect life and eyesight from its pernicious influences.

Privileges Extended to New York Society Members.

Dr. E. Eliot Harris, New York, offered the following:

WHEREAS, The New York State Medical Association and the Medical Society of the State of New York have mutually agreed by an overwhelming majority of the combined membership to ratify the agreement to consolidate in one state medical organization on the plan of the New York State Medical Association, which is practically the same as the plan of the American Medical Association; and as the officers of both state associations have signed a petition to the Supreme Court for an order consolidating them as one state medical body;

Resolved, That the members of the Medical Society of the State of New York present at Atlantic City be permitted to register as the guests of this Association, with all the privileges of participation in the scientific work of the sections; and be it further

Resolved, That a copy of this resolution be sent to the chairman of each section.

It was moved that the resolution be adopted. Seconded and carried.

Amendment of Constitution Proposed.

Dr. W. T. Bishop, Pennsylvania, offered the following, which was laid over until the next day:

Resolved, That there be reconsidered the adoption of the report of the Committee on Constitution and By-laws, insofar as it applies to lines 1 and 2, on page 10, of the printed report on Constitution, the words "its decision shall be subject to appeal to the House of Delegates," and that there be added after the word "Association," in line 1, the words, "and their decision shall be final."

Co-operative Committees on Walter Reed Memorial.

Dr. George M. Kober offered the following resolutions, which were referred to the Walter Reed Memorial Committee.

WHEREAS, The Walter Reed Memorial Association has been incorporated in the city of Washington for the purpose of securing sufficient funds to perpetuate in a fitting manner the memory of Dr. Reed in recognition of his distinguished achievements in the cause of humanity and scientific medicine; be it

Resolved, That the American Medical Association heartily endorses the object of the above-named organization in honoring the memory of an American physician whose work in point of importance and far-reaching beneficence ranks only second with Jenner's discovery of vaccination.

Resolved, That the American Medical Association earnestly recommends the appointment of a committee in all state and county medical societies for the purpose of co-operating with the Walter Reed Memorial Association in securing the necessary funds for the speedy accomplishment of this laudable undertaking.

On motion, the House adjourned until 9 a. m., Thursday, June 9.

Fifth Meeting—Thursday, June 9.

The House of Delegates met at 9 a. m., and was called to order by the President.

The minutes of the previous meeting were read and approved.

Invitation to Meet in Boston.

Dr. S. D. Presbrey, delegate from Massachusetts, and representing the Massachusetts Medical Society, extended an invitation to the Association to hold its next annual session in Boston.

On motion, this invitation was referred to the Committee on Transportation and Place of Session.

The Secretary also read a communication from the Secretary of the Massachusetts Medical Society, extending a cordial invitation to the Association to hold its next annual session in that city, which was likewise referred to the same committee.

On motion of Dr. McCormack, a vote of thanks was extended to the Massachusetts Medical Society for its invitation.

Greetings from Canadian Association.

The Secretary read the following from the president of the Canadian Medical Association: "Hearty fraternal greetings and best wishes to you and the Association from the Canadian Medical Association."

On motion of Dr. McCormack, these fraternal greetings were reciprocated.

Report of Committee on Rush Monument.

Dr. James C. Wilson, chairman, read the report of the Committee on the Rush Monument Fund:

Mr. President and Members:—Your Committee on the Rush Monument respectfully reports as follows: The monument, which has been fully described in THE JOURNAL, has been erected on the grounds of the U. S. Museum of Naval Hygiene and Medical School, in Washington, D. C., a site very appropriate and one originally designated by the Secretary of the Navy at the request of the late Dr. Albert H. Gihon, the chairman of the

The unveiling, as has been announced in THE JOURNAL, will take place on Saturday, June 11, 1904, at 5 p. m.

Addresses will be delivered by the President of the American Medical Association, the chairman of the committee and the President of the United States. Cards of invitation have been issued to the Trustees, officers and members of the American Medical Association, and to the trustees and officers of certain organizations with which Benjamin Rush was especially interested, namely, Princeton University, the University of Pennsylvania, the College of Physicians of Philadelphia, and to the Cabinet officers, the heads of departments, and medical officers of the Army, Navy and Marine-Hospital Service now stationed in Washington.

The thanks of the committee are especially due and are hereby tendered to Mr. Perry, the sculptor, Mr. Metcalfe, the architect, and to the Henry-Bonnard Company of New York for the great interest they have taken in the work of the committee, and for the most artistic and satisfactory monument.

Your committee asks permission to defer its final report until the next session of the Association.

[See report of the unveiling on page 1633.]

Report of Committee on Scientific Exhibit.

Dr. F. B. Wynn, chairman, read the report of the Committee on Scientific Exhibit.

This report, on motion of Dr. Edwin Walker, was referred to the Reference Committee on Sections and Section Work, and the Committee was instructed to consult with the Board of Trustees and to report at this session (page 1645).

The committee was extended a vote of thanks for its splendid work.

Report of Committee on Reciprocity.

In the absence of Dr. W. L. Rodman, chairman of the Committee on Reciprocity, the secretary stated that this committee desired to report progress.

Delegates to International Congresses.

President Musser read invitations (1) from the Bureau of Education at the instance of the Secretary of State, to appoint delegates from the American Medical Association to attend the International Otological Congress, which meets in August this year at Bordeaux; (2) appointment of delegates to the Roentgen Ray Congress, which meets in Berlin, 1905; and (3) an invitation from the organization committee of the International Congress of Medicine to appoint an organizing committee of twelve or fifteen to take up the organization in this country.

On motion of Dr. W. T. Bishop, the President was empowered to appoint any members as delegates who desired to attend these meetings and whom he might designate.

Resolution on Leprosy Offered.

Dr. L. Duncan Bulkley presented a resolution from the Section on Cutaneous Medicine and Surgery in regard to leprosy, which was referred to the Reference Committee on Hygiene and Public Health (page 1645).

Publications on Venereal Diseases.

The Secretary read a communication from the Section on Hygiene and Sanitary Science with reference to the publication of reports and discussions on venereal diseases, which was referred to the Board of Trustees.

Committee on Cancer Investigation Proposed.

The Secretary read a communication from Dr. Hemmeter, Baltimore, with reference to the organization and the appointment of a Committee on Collective Cancer Investigation, which was referred to the Reference Committee on Hygiene and Public Health (page 1645).

Report of Committee on Legislation.

Resolution on Purification of the Mails Adopted.—Dr. C. A. L. Reed presented the following report:

The National Auxiliary Congressional and Legislative Committee, to whom was referred the resolution]page 1643] indorsing "the action of the Postmaster-General, in enforcing the statute which prohibits the use of the United States mails for the distribution of obscene advertisements and fraudulent compounds and appliances, respectfully report that they have had the same under consideration, and that they recommend the adoption of the resolution.

On motion of Dr. Craig, the report was adopted,

Resolution on Wood Alcohol Adopted.—Dr. Reed read the following in regard to the resolution offered by the Section on Ophthalmology (page 1643):

The National Auxiliary Congressional and Legislative Committee, to whom was referred the resolution urging the proper federal and state authorities to take the necessary steps to protect life and eyesight from the pernicious influences of wood spirit or methyl alcohol and its various preparations, respectfully report that they have had the same under consideration, and that they advise the adoption of the resolution.

On motion, the report was adopted.

Report on Medicine and Food Bureau Not Concurred In.—Dr. Reed read the following:

The National Auxiliary Congressional and Legislative Committee, to whom was referred the report [page 1640] of the Committee on National Bureau of Medicines and Foods and the accompanying resolutions, respectfully report that they have had the same under consideration, and that they recommend the adoption of the resolutions.

Dr. E. Eliot Harris, New York, moved the adoption of the report and its consideration in the committee of the whole of the House of Delegates immediately. Carried. The House then went into the committee of the whole.

Dr. E. Eliot Harris, New York, was appointed chairman.

After considerable discussion, the committee arose, and the House of Delegates was called to order by President Musser.

The chairman of the committee of the whole reported to the House that the committee had instructed him to report unfavorably on the report of the special Committee on Medicines and Foods.

Journal Clearing House Commission Rejected.—He further reported instructions that the report on the communication from the Michigan State Medical Society (pages 1576 and 1579) was laid on the table.

On motion of Dr. F. W. McRae, the report of the committee of the whole was adopted, and the original Committee on Medicines and Foods discharged.

Report of Committee on Reapportionment Adopted.

Dr. W. S. Foster, chairman, presented the report of the Committee on Reapportionment which, on motion of Dr. Ellis, California, was adopted.

The Committee on Reapportionment of Delegates, for the respective states and territories for 1905, 1906 and 1907, beg leave to report as follows:

State.	Members.	Delegates.
Alabama	1295	3
Arizona	95	1
Arkansas	711	2
California	1505	4
Colorado	518	2
Connecticut	605	2

Report of Reference Committee on Constitution.

Permanent Committee on Sections Not Approved.—Dr. M. L. Harris, chairman of the Reference Committee on Constitution and By-laws, presented the following report:

Resolved, That this committee report to the House of Delegates that in its opinion a permanent committee on sections and section work [page 1640], "to direct and advise in matters of section work," "to effect and maintain needed reforms," and "to devise ways and means of preparing the programs," would interfere with the prerogatives and autonomy of the chairmen and secretaries of the various sections, and therefore do not recommend the appointment of such a committee.

On motion, the report was adopted.

Proposal to Make Trustees Active Members of House of Delegates.

Dr. R. C. Moore, Nebraska, offered the following:

WHEREAS, The members of the Board of Trustees are only *ex officio* members of this House, without a vote: therefore, be it

Resolved, That Article IX, Section 3, of the Constitution, does not apply to members of the Board of Trustees.

The resolution was referred to the Reference Committee on Constitution and By-laws, with instructions to report this afternoon (page 1645).

Report on Time of Meeting of State Associations Adopted.

Dr. J. N. McCormack said that when the chairman of the Committee on Miscellaneous Business reported (page 1640) in regard to branch associations (page 1580) at a previous meeting of the House, the action taken on that report carried with it the report of the Committee on Organization recommending the time of meeting of state associations (page 1579). He therefore moved a reconsideration of the vote taken at a previous meeting, by which this matter was postponed for one year, in order that the recommendation may go to the secretaries of state associations at once. Carried.

Dr. McCormack then moved that the recommendation of the Committee on Organization with reference to the time of meeting of state associations be adopted, and the Secretary be instructed to send copies of the recommendation to the secretaries of the various state associations. Carried.

Report on Branch Associations Held Over.

Dr. McCormack moved that the report of the committee in regard to branch associations be postponed until the next annual session. Carried.

Resolution on Prophylaxis of Venereal Diseases.

Dr. Bulkley, New York, presented the following:

The conjoint meeting under the auspices of the Committee on the Prophylaxis of Venereal Diseases of the American Medical Association recommends to the House of Delegates the following preamble and resolution, urging their adoption and wide circulation:

> WHEREAS, Syphilis and gonorrhea have been abundantly shown to be the cause of [illegible] and danger to the health and life of the com[illegible] those innocent and those guilty of sexual tra[illegible]
>
> *Resolved*, That the American Medical Association earnestly call the attention of the profession to the matter, and urge that boards of health throughout the United States give serious attention to the same, with a view to securing proper protection against these diseases by legal measures.

These were referred to the Reference Committee on Hygiene and Public Health.

On motion, the House adjourned until 2 p. m.

Sixth Meeting—Thursday, June 9.

The House was called to order at 2:15 p. m. by the President.

Report on Status of Trustees in House of Delegates.

Dr. M. L. Harris, chairman of the Reference Committee on Constitution and By-laws, reported in regard to the resolution offered by Dr. Moore (page 1644) regarding Article IX, Section 3, of the Constitution, that the Board of Trustees were members of the House of Delegates, without the right to vote.

On motion of Dr. John B. Roberts, the report was adopted.

Election of Officers.

The House then proceeded to the election of officers, with the following result:

PRESIDENT.—Lewis S. McMurtry, Louisville, Ky.

VICE-PRESIDENTS.—Edward Jackson, Denver; James Hall Bell, San Antonio, Texas; F. C. Shattuck, Boston; B. C. Pennington, Atlantic City.

SECRETARY.—George H. Simmons, Chicago.

TREASURER.—Frank Billings, Chicago.

TRUSTEES.—T. J. Happel, Trenton, Tenn.; W. W. Grant, Denver; Philip Marvel, Atlantic City.

PLACE OF MEETING.—Portland, Oreg.

ORATION ON MEDICINE.—Charles G. Stockton, Buffalo, N. Y.

ORATION ON SURGERY.—John Collins Warren, Boston.

ORATION ON STATE MEDICINE.—George Blumer, San Francisco.

Report of Reference Committee on Sections.

Honorary Members Elected.—The Reference Committee on Sections and Section Work submitted the name of Dr. A. Maitland Ramsey of Glasgow, Scotland, from the Section on Ophthalmology, and the name of Dr. A. Logan Turner of Edinburgh, Scotland, from the Section on Laryngology and Otology, who were recommended for honorary membership by those sections, with the recommendation that they be elected; and on motion, the recommendation was concurred in.

On motion, the House adjourned until 9 a. m. Friday, June 10, 1904.

Seventh Meeting—Friday, June 10.

The House met at 9:30 a. m., and was called to order by the President.

The minutes of the previous meeting were read and approved.

Report of Reference Committee on Sections.

Money for Scientific Exhibit Favored.—Dr. A. P. Ohlmacher, Ohio, presented the following report of the Reference Committee on Sections and Section Work (page 1644):

> *Resolved*, That recognizing the intense interest and great benefit to the American Medical Association of the scientific exhibit, we recommend to the Board of Trustees of this Association that an annual honorarium of five hundred dollars be granted to the director of the Scientific Exhibit.
>
> *Resolved*, In view of the fact that Dr. F. B. Wynn has made such a striking success of this exhibit, we respectfully suggest to the House of Delegates that he be continued in the capacity of director of the Scientific Exhibit.

It was moved that the report of the committee be adopted, and the recommendation contained therein be reported favorably and referred to the Board of Trustees. Seconded and carried.

Report of Reference Committee on Hygiene.

Section on Hygiene to Carry on the Prophylaxis of Venereal Diseases.—Dr. J. N. Hurty, Indiana, chairman of the Reference Committee on Hygiene and Public Health, presented the following report concerning the second annual report of the Committee on Prophylaxis of Venereal Diseases (page 1641):

> This is an able and full report, treating of the moral and economical necessity of the prevention of venereal diseases. The Reference Committee on Hygiene and Sanitary Science recommends the acceptance of the report in general, but does not indorse the suggestion that "the time has arrived for the organization of a national society for the study and prevention of venereal diseases," but believes that for the present the Section on Hygiene and Sanitary Science will be equal to the task of doing the work necessary for the opening of this important matter.

On motion of Dr. Craig, Pennsylvania, the report was adopted as read.

Committee for Cancer Research Advised.—Dr. Hurty presented the following report of the Reference Committee on Hygiene and Public Health:

> This report concerns the recommendation of Dr. Hemmeter, Baltimore, that this body appoint a committee for the collective and prophylactic study of cancer [see page 1644].
>
> Your committee indorses this recommendation, and in turn urges the appointment of such committee.

On motion of Dr. Harris, Illinois, the report was adopted.

Leprosy Study Station Advised.—Dr. Hurty also presented the report of the Reference Committee on Hygiene and Public Health, with reference to the following resolutions, proposed by Dr. Cooper (page 1644), delegate from Hawaii:

> WHEREAS, The acquisition by the United States of insular possessions, in which a considerable amount of leprosy exists, particularly in Hawaii, has increased the responsibility of the government in the case of these unfortunate beings; therefore, be it
>
> *Resolved*, That the American Medical Association urges on the Federal authorities the establishment of an experimental station, including hospital and laboratories, at the leper settlement in the Island of Molokai, Hawaii, for the investigation and study of leprosy, looking especially toward the cure of the disease.

Your Reference Committee on Hygiene and Public Health fully indorses these resolutions and urges their adoption.

It was moved and seconded that the report on these resolutions be adopted. Carried.

Report of Board of Trustees.

Medical Directory Approved.—Dr. M. L. Harris, Illinois, speaking for the Board of Trustees, said: The Board recommends that the House of Delegates consent to the publication, by the Editor of THE JOURNAL, after proper correspondence with the secretaries of state societies, and receiving their coöperation, of a directory of the members of the American Medical Association and of the state associations, by states, counties, etc.

On motion of Dr. W. T. Bishop, Pennsylvania, the recommendation was concurred in.

Amendments to Constitution Proposed—Manner of Election.

Dr. S. L. Jepson offered the following amendments to the Constitution:

Amendment to Chapter 7, Section 1 (page 7 as revised): Nominations for office, except that of the Treasurer, shall be made orally, but no nominating speech shall exceed two minutes in length. Any nominee receiving a majority of the votes cast shall be declared elected.

The Treasurer shall be nominated by the Board of Trustees.

Dr. J. N. McCormack offered the following amendments:

To amend Section 1, Chapter 4, of the By-laws by striking out Section 1 and inserting in lieu thereof the following: "*Time of Elections.*—The election of officers shall be the first order of business of the House of Delegates after the reading of the minutes on the morning of the last day of the session."

And to amend Section 3 of the same chapter by striking out said section and inserting in lieu thereof the following: "Nominations for President shall be by ballot. All other officers shall be nominated by a committee of seven, representing the various geographical divisions of the country as nearly as may be.

These will lie over until next year.

Proposed Change of Name of Materia Medica Section.

The Secretary read the following communication:

To the House of Delegates:

The Section on Materia Medica, Pharmacy and Therapeutics, at a largely attended meeting, having received the report of the change by your honorable body of the present name of the section to that of "Pharmacology," by unanimous vote, 2:30 p. m. to-day, request that the title of the Section be "Pharmacology and Therapeutics."

Accordingly, Dr. G. Eliot, Connecticut, offered the following amendment:

Proposed amendment to the By laws:. Chapter 8, Section 1: That the name of the Section of Pharmacology be changed to the Section of Pharmacology and Therapeutics.

This will lie over until next year.

Report of Judicial Council.

Dr. F. H Wiggin, N. Y., secretary, presented the following report of the Judicial Council:

The Judicial Council has received a protest in regard to the registration of Dr. J. R. Care, Morristown, Pa., and after considering the evidence presented, decided that his registration should be cancelled.

On motion of Dr. Roberts, Pennsylvania, the report was adopted.

Report of Committee on Reapportionment.

Dr. W. S. Foster, Pennsylvania, submitted an additional report of the Committee on Reapportionment (page 1644), relating to the State of New York, namely, that the General Secretary shall on May 1, 1905, obtain from the secretary of the constituent Association of the State of New York the number of members belonging to that organization, and shall apportion to that state a delegate for each five hundred of its actual active members and minor fraction thereof, which apportionment shall prevail for the years 1905 to 1907.

On motion of Dr. W. T. Bishop, Pennsylvania, the report of the committee was adopted.

Association Committees.

The following committees were appointed:

On Scientific Exhibit.—F. B. Wynn, Indianapolis, Director.

On Scientific Research.—Alfred Stengel, Philadelphia, Chairman; William Osler, Baltimore; L. Hektoen, Chicago.

On Organization.—J. N. McCormack, Bowling Green, Ky., Chairman; P. Maxwell Foshay, Chicago; George H. Simmons, Chicago.

On Rush Monument.—James C. Wilson, Philadelphia, Chairman; Henry D. Holton, Brattleboro, Vt., Treasurer; L. Duncan Bulkley, Connecticut; Frank Billings, Chicago; Wm. L. Rodman, Philadelphia.

Medical Legislation.—Charles A. L. Reed, Cincinnati, Ohio, Chairman, one year; W. L. Rodman, Philadelphia, two years; William H. Welch, Baltimore, three years.

On Transportation and Place of Session.—M. L. Harris, Chicago, Chairman; John C. Munro, Boston; G. C. Savage, Nashville, Tenn.; W. A. Jayne, Denver; H. Bert Ellis, Los Angeles, Cal.

On National Incorporation.—Joseph D. Bryant, New York, Chairman; H. L. E. Johnson, Washington, D. C.; D. S. Fairchild, Des Moines; Leartus Connor, Detroit; C. G. Kenyon, San Francisco.

On Reciprocity.—W. L. Rodman, Philadelphia, Chairman; S. D. Van Meter, Denver; Jos. M. Mathews, Louisville; T. J. Murray, Butte, Mont.; Beverly D. Harison, Sault Ste. Marie, Mich.

Judicial Council.—P. Maxwell Foshay, Chicago, one year; D. C. Peyton, Indiana, two years; F. H. Wiggin, New York, three years; George Ben Johnston, Virginia, four years; W. B. Russ, Texas, five years.

Council on Medical Education.—W. T. Councilman, Massachusetts, one year; J. A. Witherspoon, Tennessee, two years; Charles H. Frazier, Pennsylvania, three years; Victor C. Vaughan, Michigan, four years; Arthur Dean Bevan, Illinois, five years.

Time of Next Session To Be Decided.

On motion of Henry D. Holton, Vermont, the time of the next annual session was left to the President, Secretary, and Chairman of the Committee of Arrangements.

Resolution of Thanks.

Dr. J. N. McCormack, Kentucky, offered the following resolution of thanks:

Resolved, That the thanks of this Association be hereby tendered to the profession and citizens, and especially to the ladies, of Atlantic City, for their hospitality and entertainment during this session; to the presidents for the able and impartial manner in which they have conducted the business during the year in presiding over our deliberations; to the transportation companies for reduced rates; to the trustees of schools for the use of this building, and to all others who have in any way contributed to the entertainment and hospitality of the members of the Association.

On motion the resolution was unanimously adopted, after which the House of Delegates adjourned *sine die*.

OFFICIAL MINUTES—GENERAL MEETINGS.

First General Meeting—Tuesday, June 7.

The Association met at 11 a. m., at Marine Hall, Young's Pier, Atlantic City, and was called to order by President Billings.

The President invited all vice-presidents, ex-presidents and ex-vice-presidents of the Association to take seats on the platform. There were seated on the platform Drs. G. C. Savage, George F. Jenkins, Henry O. Marcy, John A. Wyeth, Joseph M. Mathews, Charles A. L. Reed, C. Lester Hall, Alonzo Garcelon, Surgeon-General Geo. M. Sternberg, W. W. Keen. and George H. Simmons.

Mayor's Address of Welcome.

Prayer was offered by the Rev. William Aikman, Atlantic City, after which President Billings introduced the Hon. Franklin P. Stoy, mayor of Atlantic City, who delivered an address of welcome.

He said, in part, that this was not the first opportunity he had had to address the members of the Association, and he felt it a pleasure and an honor, in behalf of the City of Atlantic City, to extend a hearty welcome to the seaside resort, and in extending this welcome he extended also the freedom of the city. Every effort had been put forth to make the occasion a pleasant one. During the meeting he had suspended business at the City Hall. He hoped that the members would take advantage of the freedom of the city during their stay. Again, he thanked the Association for the great pleasure in being with them, and hoped that when the members were looking over the United States for a place of meeting they would not forget that the latchstring of Atlantic City was always hanging outside. (Applause.)

Welcome from Atlantic City Profession.

President Billings introduced Dr. T. K. Reed of Atlantic City, who delivered an address of welcome on behalf of the local medical profession. Among other things, Dr. Reed said:

> Those who know our local history best say that the doctors made Atlantic City, therefore we welcome you to-day to your home, and you may well feel proud of your progeny, for she possesses health, youth and beauty. Moreover, with that rare juvenile wisdom which never fails to elicit admiration, she gives you a cordial greeting inspired by filial affection. This fair creature holds within her grasp a cornucopia of hygienic blessing.
>
> As you stand on the shore and look out on the broad and briny ocean, however, you may be tempted to quote "Water, water everywhere, and not a drop to drink." But I assure you there is a counterpoise to our dry atmosphere, and you will find an abundance of pure water, with beverages of every kind and color, both plain and sparkling, to allay your thirst and cheer your weary souls.
>
> There can be no doubt about the salubrity of our climate, and it is an undeniable fact that everybody here lives till he dies. (Laughter.) Just what would happen, though, if the American Medical Association could abide with us always, is a question. Possibly, with the aid of bacteriology and modern scientific methods, some of our inhabitants might survive the period named.

Dr. Reed said that the originator of the scheme of transforming the island into a health resort was a physician, Dr. Jonathan Pitney of Absecon. He was likewise the promoter of the first railroad to this beach. When the problem arose as to whether they should construct a dam or span Absecon Creek with a bridge, the Doctor told the engineers it would be cheaper to build a bridge, and added, "To tell the truth, Absecon is not worth a dam."

Dr. Reed concluded his remarks as follows:

> Gentlemen, your aims are high and unselfish. You are a grand brotherhood among whom there is no strife or sectional animosity. You are devotees of science, and yet your Shibboleth is the good of mankind. Your profession is the hope and reliance of every phase of humanity. Hard-working and self-sacrificing colleagues! Heroes of unsung epics, who have faced with dauntless courage deadly contagions and infections! You have stormed many a San Juan hill in your daily calling. Furthermore, you are human comforters in the hour of sickness, sorrow and affliction.
>
> In the name of the medical fraternity of Atlantic City, I extend to you a warm welcome, with the sincere wish that you may have a jovial and profitable time during your stay here, and that you will please and honor us by coming again as soon as possible. (Applause.)

Response to Address of Welcome.

Dr. G. C. Savage, Tennessee, First Vice-President of the Association, was introduced and responded felicitously to the address of welcome. He referred to the rapid growth of the Association and paid a high compliment to Dr. J. N. McCormack, saying that he deserved not only great credit, but the highest praise, for what he had done toward perfecting methods of organization. He hoped and predicted that the time would come when there would be established a department of public health by Congress, and a member of the Association be appointed as its secretary and as a cabinet officer. He thanked Mayor Stoy and Dr. Reed, as well as the citizens of Atlantic City, for the hearty welcome they had extended.

Report of the Committee of Arrangements.

Dr. B. C. Pennington, Chairman of the Local Committee of Arrangements, presented the following report:

> *Mr. President and Gentlemen:*
>
> Your committee has little to report beyond the matters submitted to you in the program. The Honorable Franklin P. Murphy, Governor of New Jersey, was to have welcomed you to our state. The Transatlantic steamer, on which he was a passenger, was long overdue. The governor sends his regrets that he cannot welcome you in person, but bids me to say to you that New Jersey extends to you a very cordial welcome, and trusts that your stay will not be without pleasure and profit.
>
> In returning to Atlantic City so soon after your last visit, we feel greatly complimented. Our aim has been to win your confidence in our ability to provide entertainment for such a large association. This association has grown to such colossal proportions that it is no light task to provide for its entertainment. The mere providing of money to meet its running expenses has been but a proportion of the work of your committee. The size of the numerous sections and the necessity of grouping them in close proximity, with the other details, too numerous to mention, has been the greatest work of your committee, and while I am sure we have made mistakes, I trust they are few and unavoidable.
>
> Your committee realized that the success or failure of this meeting depended on them, and each one has performed his part with commendable zeal and intelligence. To each one of them I extend my heartfelt thanks for their counsel and help; also to the hotel men of Atlantic City for their gift of nearly $5,000 to make this session possible.

Introduction of the Reed Memorial Fund.

At the conclusion of the reading of the report of the Local Committee of Arrangements, President Billings said:

> At the meeting held in New Orleans, the House of Delegates appointed a committee, which was known as the Major Walter Reed Monument Committee. This committee is composed of Drs. W. W. Keen, Joseph D. Bryant, Victor C. Vaughan, A. T. Cabot, T. S. Cullen, and the President of the Association was made an ex-officio member. Major Walter Reed died a year and a half ago. To the medical world no word is necessary to say of Reed to know who he was. The lay public does not know him, and I am afraid the medical public do not appreciate what he did and do not now appreciate all he did. Had Reed, as a major in the army, performed an act of conspicuous bravery of equal magnitude to that which he did for medicine, his name would never die. Had he as a civilian performed an act which would have conserved the commerce of the world to an equal degree, his name would never die. It seems to us who are interested in this subject, that this morning, when the greatest body of us

are gathered together, something should be said on this subject, and I will ask Dr. Keen, chairman of the committee, to say a word or two.

Announcement of Subscription List for Reed Memorial.

Dr. W. W. Keen said:

I shall only say a word or two in reference to the report of this committee. As a matter of fact, the Walter Reed Memorial Association is now an incorporated body in the District of Columbia. The president of it is a man known throughout the country, Dr. Daniel C. Gilman, formerly president of Johns Hopkins University, and now president of the Carnegie Institution. It is, therefore, a body thoroughly equipped for the purpose of caring for any funds which may be contributed to it. It is our hope this morning that we shall raise not less than ten thousand dollars, for this sum is requested and due from the profession which Walter Reed adorned by his splendid scientific work, and from his country to whom his services were dedicated. (Applause.)

Welch's Eulogy of Reed.

President Billings asked Dr. William H. Welch, of Baltimore, to say a few words. Dr. Welch said:

I respond with very great pleasure and enthusiasm to the invitation of the committee of this Association to say a few words concerning the necessity of stirring up the sentiment and enthusiasm of the members of the association in behalf of this great memorial to Walter Reed. His service to mankind is to be paralleled only in two or three instances. It is a service to which we can all respond with an unusual degree of enthusiasm. Every feature connected with it is one that should appeal to the members of the profession. Walter Reed himself was a man of unusual charm of personality; a man of the very highest character; a man with a pure love of truth; a man who was scientifically trained to undertake the work which he did. The discovery which he made is one which is peculiarly American. He was trained entirely in this country to undertake this work, and he undertook it with a complete and adequate training for the purpose. The work was undertaken under the auspices of our National Government at a time when we were in military control of the Island of Cuba. In addition to that, the scientific basis of the work is one which should appeal to us. It was an admirable, a classical piece of scientific investigation. No one can read the steps by which Reed reached his conclusions without feeling that the basis of the work is entirely sound, and that it was carried out by experiments of very great ingenuity.

The discovery itself, as I have remarked, has but one or two parallels in our profession. I think we can put it second to the discovery of the control of smallpox by vaccination. It means nothing less than the control of that most dreaded scourge—yellow fever. It is a discovery which rests on a scientific foundation, which has been put to a practical test, and that test has resulted in a complete extermination of yellow fever from the Island of Cuba. (Applause.) It will result in the control of the disease elsewhere. It has already produced important results in South America. In Rio, at the recent Latin-American Congress, it is interesting to note that the weight of sentiment was entirely in support of Reed's conclusions. I say, then, it is a discovery of the first magnitude, for which we have no parallel in this country. It is the conquering of a foe, a far greater foe than we conquered in the war with Spain. What was our foe there in comparison with yellow fever?

I feel that this appeal should come, in the first instance, from the medical profession. It is an appeal which will be responded to not only by the American medical profession, but by business men when it is properly presented to the great commercial bodies and business interests of this country. The chambers of commerce should contribute largely. When we consider that the cost of yellow fever in one epidemic, that of 1878, is estimated to to have exceeded one hundred million dollars, you can readily see that this is an appeal to the business men of this country who are capable of contributing much more than the members of the medical profession. This is a practical initiation of the movement here to-day. There have been preliminary steps to have members of this Association respond liberally to the fund, and it is thought that we can go before these commercial bodies to which I have referred with a prospect of success. I feel, therefore, like re-enforcing in every way the sentiment which has been expressed by Dr. Keen. The nature of the memorial is yet to be determined. It will probably be in the form of a visible monument to Major Reed. This is in the hands of an incorporated association, the members of which give every guarantee that wisdom will be exercised in the control of the funds and in the manner of use of the funds. (Applause.)

Eight Thousand Dollars for Reed Memorial.

Dr. Theodore Diller, Pittsburg, spoke briefly of the work of Major Walter Reed, after which Dr. Keen appealed to the members of the Association for personal contributions. Nearly $8,000 was subscribed. (A report of these contributions will appear in The Journal later.)

The President's Address.

President Billings said:

As the presiding officer of this Association, the last act of my official life is one that affords me as much, if not the greatest, pleasure of all, and that is to hand to a successor of strength the executive control of this Association. Ladies and gentlemen, it affords me great pleasure to introduce to you the President of the Association, Dr. John H. Musser, of Philadelphia. (Applause.)

Dr. Musser then delivered his address. (This appeared in The Journal, June 11.) The meeting adjourned.

Second General Meeting—Tuesday, June 7.

The meeting was called to order at the First Presbyterian Church by President Musser.

Dr. George Dock, Ann Arbor, Mich., delivered the Oration on Medicine. (See The Journal, June 11.)

Following the delivery of Dr. Dock's oration was a symposium regarding institutions doing research work for the science of medicine, as follows:

"The Carnegie Institution," by Dr. John S. Billings, New York City.

"The Rockefeller Institute," by Dr. L. Emmett Holt, New York City.

"The Memorial Institute for Infectious Diseases," by Dr. Frank Billings, Chicago.

"Research Work at the Harvard Medical School," by Dr. Harold C. Ernst, Boston.

"The William Pepper Laboratory of Clinical Medicine," by Dr. Alfred Stengel, Philadelphia.

These addresses will appear later.

Report of Committee on Portraits of Ex-Presidents.

Dr. J. R. Pennington, Chicago, chairman of the Committee on Portraits of ex-Presidents of the Association, stated that he had secured for the Association a portrait of another ex-President, and that Dr. John A. Wyeth would formally present the portrait to the Association. (Applause.)

Presentation of Portrait of Marion Sims.

Dr. Wyeth spoke as follows:

Mr. President, Ladies and Gentlemen:

Twenty-eight years ago Dr. J. Marion Sims presided over this Association; twenty-one years ago he died. Bound as I am by the ties of an affectionate friendship to the memory of this immortal man, I would not trust myself to speak to you of his personal character and private life, so tender, noble and true. And what need is there for me to speak to members of this Association of his professional career, from the humble beginning in the log cabin in a newly-settled district of Alabama to become the leading surgeon of the metropolis of the western continent and thence to the capitals of Europe and the palaces of emperors and kings. In presenting to you, at the request of this Association, this portrait, the gift of his daughter, let the words of a famous co-laborer in the field of gynecology, Prof. T. Gaillard Thomas, go with it. Three years ago, in speaking to the graduating class of the medical department of Cornell University, he closed an eloquent address with these words: "If I were called on to name the three men who in all history had most benefited mankind, I would say, Edward Jenner, George Washington and Marion Sims." (Applause.)

Dr. Pennington then unveiled the portrait of Dr. Sims amid prolonged applause.

On motion of Dr. Victor C. Vaughan, Michigan, a hearty vote of thanks was extended to Mrs. John A Wyeth for the presentation of the portrait of her father.

The meeting then adjourned.

Third General Meeting—Wednesday, June 8.

The meeting was called to order at 7:40 p. m. in the First Presbyterian Church by the First Vice-President, Dr. G. C. Savage, Nashville, Tenn.

Oration on Surgery.

Dr. W. J. Mayo, Rochester, Minn., delivered the Oration on Surgery (printed in The Journal June 11), after which there was a symposium on "Mutual Relations and Duties of Government Medical Service and the Profession."

Symposium on Government Services.

Short papers were presented as follows:

What Can the Medical Departments of the Army, of the Navy, and of the Public Health and Marine-Hospital Service Do for Medical Science? By Dr. V. C. Vaughan, Ann Arbor, Mich.

What Can the Medical Profession Do for the Army? By Dr. William C. Borden, Major Surgeon, U. S. Army.

What Can the Medical Profession Do for the Navy? By Surgeon C. F. Stokes, U. S. Navy.

What Can the Medical Profession Do for the Public Health and Marine-Hospital Service? By Surgeon-General Walter Wyman, U. S. P. H. and M.-H. S.

On account of the length of these minutes, these addresses are held until a later issue for publication.

The meeting adjourned.

Fourth General Meeting—Thursday, June 9.

The meeting was called to order at 7:40 p. m. by the Second Vice-President, Dr. Isadore Dyer, New Orleans, who introduced Dr. H. M. Biggs, New York City.

Oration on State Medicine.

Dr. Biggs delivered the Oration on State Medicine, following which was a symposium on The Departments of Scientific Research of the Government.

Bureau of Animal Industry.

Dr. William H. Welch, Baltimore, spoke of "The Bureau of Animal Industry and Its Service to Medical Science," saying that this bureau was founded in 1884 for the purpose of promoting animal industry in this country and for the investigation, study and control of those diseases of animals which caused the greatest losses. The diseases of animals were in part those to which human beings were also subject. Comparative pathology, which was represented in the Bureau of Animal Industry, bore close relations to human pathology. He spoke of the possibility of great light being shed on the problems of medicine by studying and investigating the diseases of animals. Not a few of the diseases of animals, such as trichinosis, glanders, anthrax, rabies, and above all, tuberculosis, might affect human beings.

Since he had been in Baltimore he had been in close relation with the bureau and was more or less familiar with the scientific work carried on by it. The bureau had practically eradicated from this country that great pestilence of cattle, namely, pleuropneumonia, a disease which had caused a loss to cattle raisers in this country running up into millions of dollars annually. Fortunately, the disease had not extended west of Chicago through the vigilant and untiring efforts of the bureau.

He was also familiar with the work of the bureau in the study of hog cholera, and said that most important scientific work regarding this disease had been done by those actively connected with the bureau. Indeed, it might be said that the bacillus of hog cholera was discovered by the Bureau of Animal Industry.

Speaking of rabies, he said that Dr. Salmon had proven by trustworthy statistics that this disease is not uncommon among lower animals, and had pointed out measures for regulating its spread. He referred to the excellent work done by Stiles in regard to animal parasites. Over ten years ago some of the most important problems relating to animal tuberculosis and its relation to human tuberculosis were taken up. Dr. de Schweinitz, one of the pioneer workers in the department, had pointed out that artificial immunity could be brought about by the use of attenuated cultures. Behring believed that by the application of this method it was possible to control the spread of this disease among cattle.

The bureau is to be congratulated, he said, on the excellent work it has done, and should receive the support of the medical profession of this country in its behalf. Dr. Welch expressed the hope that our national legislators would take as much interest in the study of human diseases as they had already manifested in the study of animal diseases.

Dr. D. E. Salmon, chief of the bureau, then read a paper on "What the Medical Profession Can do for the Bureau of Animal Industry." This is reserved for later publication.

Bureau of Chemical and Medical Science.

Dr. H. W. Wiley, Washington, D. C., discussed the "Bureau of Chemistry and Medical Science." Among other things, he stated that the Bureau of Chemistry undertook many investigations which were closely related to medical science. Many of these were mentioned. He referred to the great problem of the disposal of garbage in large cities, and stated that if some economic method could be devised which would make it easier of accomplishment, great good will have been done. He discussed the problem of disposal of sewage, and of the investigations and examinations carried on by the bureau with reference to every kind of human food almost for adulterations and sophistications, saying that numerous bulletins had been published containing the results of these investigations. He said almost all forms of food were, to a large extent, subject to adulteration, and spoke of the manner in which food products were controlled in this country. The bureau was endeavoring to aid the states in their fight against the domestic adulteration. Another thing was the inspection and control of drugs carried on by the bureau. Congress had authorized the Bureau of Chemistry to inspect drugs in regard to their adulteration, not only those made in this country, but those made abroad. The bureau was doing all it could to expose secret nostrums and to determine the character of the remedies used. Secret remedies were great evils. Drugs should be dispensed by reputable physicians; laymen were not capable of prescribing for themselves by means of the circulars and advertisements of the character which usually reached them through the mails. The Association could help the Bureau of Chemistry in many ways by supporting it in the prosecution of its work.

Dr. H. D. Geddings of the United States Public Health and Marine-Hospital Service, Washington, D. C., read a paper on "The Hygienic Laboratory of the Marine-Hospital Service," which will be published in The Journal later.

The meeting then adjourned.

Closing General Meeting—Friday, June 10.

The General Meeting was called to order by President Musser at noon. He congratulated the Association on the closing of what had been in many respects the most successful convention the Association had ever held. In numbers it exceeded all others.

The symposia, which were a novel feature of the meetings, had been most instructive and of such worth that they would be continued at future sessions. They had served to make the members realize that they came to the session not for the sake of the evening entertainments or for the nightly joys of this great seaside resort, but for mental stimulus.

With these few remarks the General Meeting adjourned.

New Members.

List of new members for the month of May, 1904:

ALABAMA.

Fonde, G. H., Mobile.
Fields, E. T., Ensley.
Broughton, L. E., Andalusia.

ARIZONA.

Coleman, J. W., Jerome.

ARKANSAS.

Scott, E. M., Hamburg.
Eberle, J. G., Ft. Smith.
Jenkins, J. S., Rendleton.
Norman, Wm. S., Hamburg.
Strong, J. C., Forrest City.
Harrison, F. E., Fordyce.
Hare, J. L., Wynne.
Markham, R. A., Paragould.
Simpson, A. R., Corning.

CALIFORNIA.

Downs, A. J., Los Angeles.
Kress, G. H., Los Angeles.
Leonard, E. L., Los Angeles.
Williams, Thos. A., Oakland.
Liliencranz, Guy H., Oakland.
Cross, Chas. V., San Francisco.
Fehlen, Aug., San Francisco.
O'Neil, A. A., San Francisco.
Lyon, S. B., Los Angeles.

COLORADO.

Dennis, F. L., Colorado Springs.
Coleman, O. E., Ft. Collins.

CONNECTICUT.

Hoyt, Curtiss C., Bridgeport.
White, Benj. W., Bridgeport.
Lauder, Robert, Bridgeport.
Thompson, Emma J., Hartford.
McCook, J. B., Hartford.
Stern, Chas. S., Hartford.
Steiner, Walter R., Hartford.
Craig, William G., Hartford.
Van Strander, W. H., Hartford.
Bacon, Leonard W., New Haven.
Maher, Stephen J., New Haven.
Nadler, Alfred G., New Haven.
Creemer-Peckham, Lucy M., New Haven.
Kingman, Jas. H., Middletown.
Diefendorf, Allen Ross, Middletown.
Mitchell, J. T., Middletown.
Mountain, J. H., Middletown.
Wells, E. A., Hartford.
Griswold, Fredk. P., Meriden.
Bradstreet, Edw. T., Meriden.
Cooke, Jos. A., Meriden.
Avery, Amos, Hampton.
Delaney, W. J., Naugatuck.
Holmes, Geo. J., New Britain.

DELAWARE

Robin, Albert, Wilmington.
Lewis, Dorsey W., Middletown.

FLORIDA.

Rush, Jos. D., Orlando.
Green, I. T., Tampa.
Cravey, J. Z., Pensacola.

GEORGIA.

Strickler, Cyrus W., Atlanta.
Armstrong, Wm. B., Atlanta.
Ward, C. Pelham, Atlanta.
Deadwyler, M. P., Maysville.
Ware, D. B., Fitzgerald.

IDAHO.

Albee, D. P., Oakley.
Bocek, John, Boise.
Compton, F. W., Meridian.

ILLINOIS.

Nickelsen, G. A., Chicago.
Forrester, Jos., Chicago.
Blatchford, F. W., Chicago.
Teel, Ambrose W., Chicago.
Bernhardt, A. P., Chicago.
Pietrowicz, S. R., Chicago.
Bosler, Arthur G., Chicago.
Mullan, Eugene A., Chicago.
Caps, J. A., Chicago.
Franklin, Isaac J, Chicago.
White, Arthur W., Paxton.
Duncan, J. W., Pawnee.
Agler, Frank S., Bentley.
Taylor, Geo. G., Elkhart.
Dakin, R. G., Magnolia.

INDIANA.

Reser, W. M., La Fayette.
Stover, C. J., Eaton.
Lindenberger, I., French Lick.
Sharrer, H. E., Hammond.
Truitt, Frank L., Noblesville.
Willits, A. J., Lowell.
Kamann, G. H., Seymour.
Didlake, M. T., Monticello.

IOWA.

Matthey, H., Davenport.
Kinnier, Lily, Dubuque.
Rood, L. D., Des Moines.
Bickley, W. H., Waterloo.
Bullock, A. H., Cushing.
Alton, W E., Ft. Dodge.
Van Gordon, Jesse L., Emmetsburg.
Dittmer, H. A., Manchester.
Dittmer, E. G., Manchester.
Nicol, J. H., Manchester.

KANSAS.

Greer, T. D., Edgerton.
Bowers, Chas. E., Wichita.

KENTUCKY.

Wilson, Dunning S., Louisville.
Trawick, J. D., Louisville.
Bruner, W. T., Louisville.
Brandeis, Florence, Louisville.
Thomasson, W. J., Newport.
Huddle, Garland E., Bowling Green.
Cecil, G E., Flat Lick.
Foley, Thos. S., Pineville.

LOUISIANA.

Butterworth, W. W., New Orleans.
Hummel, E. M., Jackson.

MAINE.

Stubbs, R. H., Augusta.

MARYLAND.

Sampson, J. A., Baltimore.
Rosenthal, M. E., Baltimore.
Herring, A. P., Baltimore.
Stokes, Wm. R., Baltimore.
Brooke, Roger, Sandy Spring.
Lewis, John L., Bethesda.
Gray, Oliver J., Hebron.

MASSACHUSETTS.

Bridgman, Burt N., Boston.
Fairbanks, A. W., Boston.
Allen, G. W., Boston.
Reardon, T. J., Boston.
Victor, Agnes C., Boston.
White, Leon E., Boston.
Lovett, R. W., Boston.
Smith, P. M., Boston.
Van Allen, H. W., Springfield.
Devine, W. H., South Boston.
Black, G. L., Lawrence.
Bacon, Theo. S., Springfield.
Trowbridge, Edw. H., Worcester.
Shattuck, A. M., Worcester.
Flood, Everett, Palmer.
Robertson, Fredk., Melrose.
Truesdale, P E., Fall River.
Hunt, George P., Pittsfield.

MICHIGAN.

Haines, B. M., Three Rivers.
Remillard, J. L. P., Iron Mountain.
Gowdy, F. M., St. Joseph.
Wilson, Wm. L., St. Joseph.
Jenison, Chas. O., Greenville.
Snow, S. A., North Branch.
Fay, George E., Detroit.
Rosenthal, Jacob, Sault Ste. Marie.

MISSISSIPPI.

Montgomery, J. S., Starkville.
Cooper, I. W., Newton.

MISSOURI.

Kare, R. Emmet, St. Louis.
Padberg, L. R., St. Louis.
Nicks, H. G., St. Louis.
Link, J. J., St. Louis.
Dunlap, W. O., Sedalia.
Wright, Chas. O., Grandin.
Norman, J. B., California.
Widner, A. W., Newtown.
Collins, M. T., Sedalia.
Baker, N. F., Fulton.
Hickerson, E. R., Moberly.
Osborn, J. F., Henry.

NEBRASKA.

Chapman, W. H., Hastings.
Gibbons, C. K., Kearney.

NEW HAMPSHIRE.

Flanders, Chas. F., Manchester.

NEW JERSEY.

Graham, W. H., Atlantic City.
Hirst, L. B., Camden.
Marcy, F. W., Camden.
Van Selver, J. E. L., Camden.
Iszard, Wm. H., Camden.
Clark, J. H., Newark.
Roeber, W. J., Newark.
Schlichter, C. H., Elizabeth.
Hedges, E. W., Plainfield.
Smith, J. A., Blackwood.
Nalitsky, D. I., Bayonne.
Marcy, V. M. D., Cape May.
Rogers, Alex. W., Paterson.
Ware, J. W., Bayonne.
Long, Monroe B., Plainfield.
Synott, M. J., Montclair.
Todd, Francis H., Paterson.
Garrison, Jos. E., Ocean City.
Towar, Chas. G., Atlantic City.
Voorhees, Shepard, Newton.
Tunison, G. O., Oxford.

NEW MEXICO.

WISCONSIN.

Schofield, H. R., Greenwood.
McMahon, J. P., Union Grove.
Hansen, Chas. O., Neenah.

Society Proceedings.

COMING MEETINGS.

Wisconsin State Medical Society, Milwaukee, June 22.
American Ophthalmological Society, Atlantic City, July 13.
Washington State Medical Association, Seattle, July 13-15.

AMERICAN ACADEMY OF MEDICINE.

Twenty-ninth Annual Meeting, held in Atlantic City, N. J., June 4, 5 and 6, 1904.

The President, Dr. John B. Roberts, Philadelphia, in the Chair.

Report of Council.

One recommendation of the report was that societies with a sociologic trend be invited to send delegates to the meetings of the Academy, and to take part in the scientific business. It was further suggested that a committee be appointed to prepare a list of colleges whose degrees are acceptable to the Academy. The report was adopted as a whole, and the President appointed the following committee: Drs. Winfield S. Hall, Chicago; Donly C. Hawley, Burlington, Vt.; W. Jarvis Barlow, Los Angeles, Cal.; Charles McIntire, Easton, Pa., and Charles L. Van Pelt, Toledo, Ohio.

National Bureau of Medicines and Foods.

The Secretary read the report of council on the paper of Dr.

H. Bert Ellis, Los Angeles, on "Necessity for a National Bureau of Medicines and Foods," which had been read at the last meeting. It was recommended that further thought be given to the plan, hoping that a thoroughly practical scheme could be worked out, and that in the meantime the Academy take no action. A short discussion favorable to the subject followed, by Drs. Ellis, Leartus Connor, Dr. Philip Mills Jones, secretary Joint Committee of Medicines and Foods, American Medical Association and American Pharmaceutical Association. On motion the report was adopted.

Medical Licensure.

Dr. Charles McIntyre, secretary, gave in part the results of state examinations for medical licensure, for 1903. The results from 26 states showed that 2,478 licenses had been issued, and that 445 applicants had been refused, making a total of 2,923 applicants.

Relations of Dentistry and Medicine.

Dr. Edward C. Kirk, dean of the Department of Dentistry, University of Pennsylvania, said that dentistry is essentially a department of the healing art, and includes the treatment of all pathologic conditions of the teeth and their associated parts, as well as that class of restorative procedures known as dental prothesis or mechanical dentistry. The problems of dentistry in pathology and therapeutics, are the same in principle as those which confront the medical practitioner. For this reason the sciences fundamental to medicine are fundamental to dentistry. The author pointed out that the relations of dental and oral diseases to bodily health should command the serious consideration of the medical practitioner, and that the oral manifestations of systemic disease should be recognized by the practitioner of dentistry. It seemed to him infinitely important that there should be a general recognition of the need for a closer interrelationship between medicine and dentistry, based on their possibilities for mutual helpfulness.

Relation of Physicians to Dentists.

Dr. John S. Marshall, U. S. Army, in a paper read by Dr. Alexander R. Craig, considered the subject from the professional and ethical standpoints. He quoted definitions of physician, medicine, surgery, dentist and dentistry. Exception was taken to the definition of dentistry and the following offered: "That department of medicine and surgery which relates to the study of the diseases, injuries and irregularities of the teeth, their treatment and preservation, the replacing of lost teeth by artificial substitutes, and the treatment of the diseases, injuries and deformities of the oral cavity, the jaws and the accessory sinuses." The education of the dentist is comparable to that of the physician, and the dental surgeon may be classed as a specialist in medicine. From the ethical standpoint the same claim holds for the true dentist.

Ethical Pharmacy.

Dr. A. L. Benedict, Buffalo, described the present type of drug store, with its varied assortment of merchandise and methods of advertising ready-made remedies. He said it was usually a telephone station, a branch post-office, express office, a place to pay gas bills, circulating library and laundry. These conditions are endured by the physician because they seem impossible of correction. The druggist is not always able to execute his own wishes, because the store must be popular with the public. For the solution of the problem it is suggested that a man be found who is willing to limit himself to prescription work, and that he be given the patronage of a sufficient number of physicians to support his venture. It is obvious that this would diminish the number of pharmacists in any community, as they all would not be able to earn a living on the profits of prescriptions alone.

Protest Against Proprietary Products.

Dr. A. Mansfield Holmes, Denver, considered this subject in the light of "Mysticism vs. Rational Therapeutics." He referred to the methods employed by unscrupulous manufacturers of proprietary products. Other questions treated were whether the manufacture and sale of nostrums should be under legislative control, and to what extent it should be carried should a national bureau of medicines and foods be established. If so, how such a bureau should be selected and with what authority it should be invested. The relation of the nostrum syndicate to the public was mentioned and inquiries made as to the protection of so-called "private formulæ." He believes that steps should be taken to encourage original research and to reward brilliant discoveries in medicine and therapeutics. He also believed that the government should protect its citizens by legislating against the manufacture and sale of worthless and dangerous secret nostrums. He suggested that the academy should formulate practical plans to aid in bringing about the establishment of a national bureau of medicines and foods.

Synonyms in the New Pharmacopeia.

Dr. Joseph P. Remington, chairman of the committee of Revision, Philadelphia, discussed the effects of synonyms on the practice of medicine, and the relation of the pharmacist to physicians and to the public. He considered it desirable to drop these unscientific common names, because of the difficulty of compelling druggists to make and sell preparations of the standard strength. He shows that in those states where there are laws compelling adherence to the U. S. P., the use of synonyms affords loopholes for dishonest druggists. In conclusion, he called the attention of physicians to the importance of carefully noting changes in official nomenclatures, and the necessity for greater care in the use of official titles in writing prescriptions.

Science and Shekels.

Dr. Charles McIntyre, Easton, Pa., stated that the contest between shekels and science is one of the great stumbling-blocks in the way of the proper relation between pharmacist and physician. The physician is not unlike the rest of humanity in not wishing to confess ignorance on subjects he is reputed to know, therefore in straits he will try medicines of unknown composition, because of their reputed value. One way of bettering this condition is suggested by putting the responsibility of the character of the preparation on the druggist who, as a rule, when put on honor can be trusted.

DISCUSSION.

Dr. William R. White, Providence, R. I., opened the discussion on these papers. He cited a suggestive case in which apparently a life had been sacrificed, because the oral condition had not been recognized sufficiently early, and expressed the belief that the medical profession could not too promptly make a point of being more accurate in differentiating troubles which may possibly originate in the mouth and call in the scientific dentist for his diagnostic ability and technical skill.

Dr. Eugene S. Talbot, Chicago, said that the dentist of the future must be as well grounded in the fundamental principles of medicine as other specialists, which should be taught in a regular medical college with medical students. The general welfare of a patient is based on a healthy mouth. He doubted the possibility of a successful operation along the alimentary tract with pus germs circulating throughout the canal from diseased gums. He believes that medical colleges should have a chair of stomatology, where 16 to 20 lectures should be given on the pathology and treatment, including hygiene, of the mouth and teeth.

Dr. L. Duncan Bulkley, New York, said that dentists should be made acquainted with those lesions in the mouth due to syphilis. Interstitial gingivitis could sometimes be cured by judicious internal treatment.

Dr. Henry O. Marcy, Boston, suggested that for the relief and cure of disease there should be a consolidation of the knowledge of dentists and physicians.

Dr. S. A. Knopf, New York, felt that the word "interdependence" covered the relationship between medicine and dentistry. He believed that some mixed infections in pulmonary tuberculosis could be traced to decayed teeth. He quoted a list of much-advertised remedies which analysis had shown to contain from 20 to 40 per cent. of alcohol. Lawyers and ministers, without due consideration, willingly signed their names commending these products. He felt it quite within the province of the Academy to send out a warning to these gentlemen to stop prescribing medicines.

President's Address.

Dr. John B. Roberts, in his address on "The Doctor's Duty to the State," called attention to the need of honesty in the profession, both in professional matters and in civic duties. He pointed out the fact that the special training of physicians to know the needs of the community gave them unusual personal influence, and therefore increased their responsibility to the state. A physician should not be satisfied with simply treating the sick, but should endeavor to insist on the correction of hygienic evils in the community in order to prevent ill health. Attention was called to the political corruption so prevalent at the present time, and illustrations were given of the widespread inertia among business men in regard to fighting political evils. The growing distrust, even of judges, was mentoined, and the profession was urged to take an active part in political duties. Medical men should insist on mental hygiene as of equal importance with physical hygiene in the maintenance of the health and happiness of the individual. The dishonesty to the patient due to doctors prescribing secret remedies was referred to, and quotations given to show how largely the vaunted secret remedies are made up of alcohol and coal-tar preparations. The profession was urged to make vigorous efforts to discourage the use of remedies of which the active ingredients were unknown to the prescriber.

Teaching of Hygiene in Public Schools.

Dr. Helen C. Putnam, Providence, R. I., gave an analysis of the laws of the various states.

Medical Inspection in Public Schools.

Dr. Edward Jackson, Denver, said that school hygiene must include attention to actual disease within the schools and provision for its treatment; the immediate suppression of epidemics; the recognition of all physical defects among the pupils, with steps to secure their correction; maintenance of the best sanitary conditions throughout the whole school environment of the child, the training by verbal instruction, exercises and habitual practice of general and individual hygiene, and inspiring in every scholar the same reverence for health that we seek to instil with regard to patriotism or moral obligation. Defects of sight and hearing should be systematically sought for once a year among all pupils. Medical inspection of schools will be best done by a distinct class of practitioners who devote their whole time to this and similar work.

DISCUSSION.

Dr. James T. Searcy, Tuscaloosa, Ala., spoke of his particular interest in the growth of the text-books in their reference to the effects of alcohol and anodynes on the human system. He felt that the principal thing to be emphasized was the effects on the brain.

Dr. De Lancey Rochester, Buffalo, thought it better that physiology should be dropped out of the public schools rather than have the poor attempt at teaching it which prevails at present. The difficulty lies in the fact that the teacher has not sufficient time or equipment for the proper teaching of this branch.

Dr. Henry O. Marcy, Boston, believed that the text-books used to-day a great deal better than those of ten years ago.

Dr. Winfield S. Hall, Chicago, suggested that the Academy ask the publishing houses to bring the series of text-books up to the latest scientific and pedagogical light on the subject; and, also ask the normal schools to prepare men and women to teach physiology. The suggestion was referred to the council for action.

Are Modern School Methods in Keeping with Physiologic Knowledge?

The symposium on this subject was opened by Dr. A. Lapthorn Smith, Montreal, whose paper was entitled: "Is the Present Method of Educating Girls Consistent with Their Physiologic Development, and Is It for the Welfare of the Race?"

Dr. Smith admitted that every child should receive an elementary education, which should be the same for boys and girls, provided that it be given in such a manner as not to interfere with their physical development. As all higher education entails more or less loss of bodily health, he advocated less higher education, more manual training; simpler methods of living; earlier marriages and more children. Higher education may be justifiable in the case of men, if it the better enables them to earn a living and to support a wife and family. As the manifest destiny of women is to become happy wives and mothers and homemakers, any education which renders these duties or privileges distasteful, or physically impossible is unjustifiable. Higher education does render wifehood and motherhood distasteful, difficult and even impossible. In conclusion he stated that his remarks did not apply with the greatest force to the greater colleges, such as Bryn Mawr and Vassar and to the universities where so much attention was paid to the physiological development of girls, but to the high schools in which girls were competing as teachers and among whom the mental strain was making physical wrecks.

Is Equal Treatment of the Sexes Best, or Do Girls Require the Same Treatment as Boys?

Dr. Stephen H. Weeks, Portland, in his paper, which was read by the secretary, said that education in its most extended signification is the art of developing the various physical, intellectual, esthetic and moral faculties. There is a radical difference, both psychical and physical, between the sexes, which training can not remove. On the subject of higher training the following questions are suggested: Shall a girl receive a college education? Shall she receive the same kind of a college education as a boy? Shall she be educated in the same college? In answer to the first query depends on the character of the girl, precisely as with the boy. The needs of our time are for the best that can be given. If the question asked under the second heading means an equal breadth and thoroughness, the answer is yes; if precisely the same course, no Answering the third question President Hyde is quoted with approval that "coeducation is worst, coördinate education is better, and separate education is best" for the woman. The young woman should not be led to indulge in the more strenuous forms of physical culture. Our real interests lie in better and more noble training of our young people; in making our young men more manly; our young women more womanly; our land more godly.

Gynecologic Aspect of Mental Overstrain at Puberty and Its Influence on Development.

Dr. William E. Darnall, Atlantic City, said that along with the school strain there are usually other causes aiding the school breakdown, such as improperly regulated home life, unwise parental guidance, improper diet, etc The girl should have special care in her education at puberty. This forced education at this period leads to flabby muscles, poorly developed lungs, weak heart, etc. Watchful study of the girl and regulation of her life as her necessities demand, are suggested as preventive means. Not until teachers and parents remember that health is more important than knowledge; not until schools realize the futility of the forcing process of education and guard the health of their girls by diminishing rather than increasing the work of the pubescent period; not until they appreciate more fully that a sound mind depends on a sound body, can we hope to diminish the pitiable array of suffering neurotics and sexual incompetents who so largely constitute the womanhood of the land and who are to be mothers of the men of our country.

Effect of Modern School Methods on the Health of the Teacher.

Dr. Jane L. Greely, Jamestown, N. Y., said that the "dead line" of modern teachers is reached too soon. The causes of rapid wear may be the essential nature of the work, the range of the subjects covered, the increase of miscellaneous duties, and the pressure of inflexible standards. Possible remedies suggested are slower preparation, relatively greater emphasis on essentials, fewer pupils and better pay. The physician should urge the importance of relaxed tension, personal hygiene, the proper use of a vacation. The present normal course emphasizes as the chief aim of teaching the development of the child's mind rather than the imparting facts, yet it is doubtful whether the average teacher understands how to let a mind grow and consequently how to relieve her own of a considerable element of tension. The teacher should have more training in the philosophy of patience, should comprehend the personality of the instructor and the poise and temper of his mind have more vital bearing on the welfare of his pupil than the eager storing up of facts. If the training of teachers brought about a certain depth of philosophy in place of a part of their enthusiasm for results, it would add years to the endurance of their nervous system and a world of benefit to their students.

DISCUSSION.

Dr. Winfield S. Hall, Chicago, believed that Dr. Greely had struck the keynote to modern pedagogy and to those changes which modern school methods must undergo. He wished that her paper might be given the widest possible circulation.

Dr. Thomas D. Davis, Pittsburg, felt that a serious difficulty lay in the fact that the teacher was expected to bring the scholars of varying degrees of intellect up to the same level of proficiency in their studies. Another difficulty was that parents load their children down with so many studies outside of those of the school room, and with social engagements.

Dr. Leartus Connor, Detroit, believed that a great fault lay in the fact physical labor is too often considered a degradation and that too much emphasis is placed on the professions as the vocations of choice.

Dr. Victor C. Vaughan, Ann Arbor, said while there was much at fault in our system of public education, there was in it much of good. It seemed to him that one of the commonest things in the American universities was the dignity of labor; the men who worked in the shops were just as respectable as those taking classical courses. In his experience in the Spanish-American war he was much pleased when told that the men digging the trenches were largely Harvard and Princeton men. He did not believe that higher education, properly conducted, hurts girls at all.

Dr. James H. McBride, Pasadena, Cal., believed that if teachers would be a little broader in their aspirations for general education, becoming well rounded out intellectually, there would be a great decrease in nervous breakdowns among them.

The Correspondence Treatment of Disease.

Dr. Fredrick T. Rogers, Providence, R. I., spoke of this method as a form of charlatanism, the natural outgrowth of the so-called correspondence schools and the lavish advertising of nostrums in the daily press. A description was given of the methods employed and an explanation given of how apparently fair propositions contain a saving clause in the interest of the advertiser. The results of some personal investigations were given. The remedy was suggested of giving great publicity to the plan, of indicating to patients the foolishness of such claims, of publicly denouncing the methods employed, criticizing the editor who plays a part in the shameful procedure, and by word, pen and example attacking at every opportunity those who by such false pretenses and absurd promises are a menace to the public welfare.

How May the Public School Be Helpful in the Prevention of Tuberculosis?

Dr. S. A. Knopf, New York City, considered the duties of the school board concerning the location, construction and equipment of the modern school house with a view to prevent the development and the spread of tuberculosis among school children. He referred to the duties of the superintendents in the arrangement of the curriculum so that the physical development is not neglected nor the intellectual faculties overtaxed. The method in which the school teacher should impart knowledge of the cause, prevention, and even cure of tuberculosis to the children was outlined, together with the duties of the school physician in regard to the prevention of tuberculosis among the children. The public school should become a great and beneficent factor in the combat against tuberculosis as a disease of the masses. He suggested the possibility of providing the children of the poor with a luncheon of a few meat sandwiches and one or two glasses of good milk. To prevent a pauperizing tendency a few pennies might be charged for these lunches. This practice, the author said, was in vogue in Boston, in Rochester and in other cities.

THE CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held May 24, 1904.

The President, Dr. Thomas W. Huntington, in the chair.

Action of the Saline Cathartics.

Dr. J. B. MacCallum described the experimental studies which he had made along these lines. The old theory of Liebig, that the saline cathartics act by raising the osmotic pressure of the intestinal contents, has been disproved, and the more modern theory of Schmiederberg, that they act by preventing the absorption of fluid from the intestines, has also but little in its favor. The purgative salts will produce catharsis when introduced intravenously in animals. Indeed they act more energetically and more quickly than if they are introduced into the stomach or intestines. Not only is peristalsis increased, but the secretion of fluid into the intestines is directly stimulated. Similar effects may be produced on a loop of intestine by painting the peritoneal surface with a cathartic solution. The salts which produce these effects are mostly calcium precipitants, such as the sulphates, oxalates, etc. The citrates do not precipitate calcium, but render it inactive in some other way. For this reason they prevent the coagulation of blood. The effects of all these salts may be neutralized by infusions of calcium chlorid. The powerful cathartic action of barium chlorid apparently does not depend on any relationship to calcium, and its action, though diminished by calcium salts, can not be entirely inhibited thereby. The same salts which act as cathartics also act as diuretics, and their action is diminished or inhibited by infusions of calcium chlorid. Even the normal flow of urine may be lessened by such an infusion. Infusions of sodium chlorid solution not only act as diuretics, but also increase the secretion of fluid into the intestines. Large infusions may cause glycosuria and correspondingly may produce an excretion of sugar into the intestines. A lack of calcium seems to increase the activity of the tissues, and an excess seems to diminish the activity, whereas sodium salts produce an opposite effect. A solution of cascara sagrada, rendered neutral or slightly alkaline by sodium carbonate, will act as a cathartic if injected intravenously. A number of practical therapeutic suggestions follow from this work. Intravenous or subcutaneous injections of cathartics may be useful in certain cases. Calcium salts may prove of value in nervous diarrhea or polyuria. The addition of calcium salts to enemata may assist in their retention.

Dr. J. M. Moss said that it was strange that barium and calcium, which are in the same class chemically, should produce such opposite results.

Dr. C. Quinan considered barium a powerful heart poison and believed that this might in some way account for its apparent antagonism to calcium. He had tried calcium chlorid on a case of chronic diarrhea without any marked results.

Dr. MacCallum in closing the discussion said that magnesium chlorid and strontium chlorid both act in a similar manner to calcium chlorid, but for some unknown reason, barium chlorid has an entirely different physiologic action. The latter has been recommended as a heart stimulant. In large doses it is very poisonous, although this toxicity is lessened by combining it with sodium chlorid. The author's father has used calcium chlorid in doses of ten grains, four times a day in eight cases of diarrhea in an insane asylum with some benefit.

Report of a Case of Hip-Joint Disease Treated by Early Operation.

Dr. T. W. Huntington stated that, under the present method of treating hip-joint disease, the results are often most disappointing. In a very large percentage of the cases, the best that can be hoped for or promised is permanent impairment of the joint, shortening of the limb, and faulty locomotion. The present knowledge of the pathology of the disease points definitely to a primary osseous focus in more than 90 per cent. of the cases. The seat of this osseous focus occurs usually in the head of the femur. The determination of the exact location of the focus is not always within the range of possibilities, but with the perfection of *x*-ray technic, ultimately much may be accomplished so far as early diagnosis is concerned. If there be any reasonable hope of a true cure for hip-joint disease, it must depend on a bold attack on the disease in its incipiency, before the synovial cavity has been invaded. Such an attack must be instituted through a channel remote from the joint capsule, and must be so planned that it will afford relief of tension, and admit of complete removal of infected tissues. The following case illustrates the proposed plan of attack.

The patient, a delicate boy of 16 years, came under observation five weeks after he had begun to complain of pain and tenderness in the right hip. The pain has gradually increased, he has had fever, and has lost twenty pounds. He now lies with the right thigh well flexed and there is marked tenderness over the great trochanter. Believing that the main trouble lay in the head of the femur, an immediate operation was decided on. The great trochanter was uncovered by a vertical incision three inches long, and after carefully reflecting the periosteum, a window was chiseled out, 2½ cm. long by 1½ cm. wide. Through this a bone curette easily penetrated the neck of the femur, and a well-defined cavity in the head of the bone was emptied of thick, yellow, purulent fluid. The bone was then curetted and treated with pure carbolic acid and 95 per cent. alcohol. The calcined bone packing of the wound broke down, but otherwise the convalescence was uneventful. In six weeks the wound was entirely closed, and the patient left for home at the end of two months, having gained eight and a half pounds. He now walks with a cane without a limp and he has recovered nearly all his lost weight.

DISCUSSION.

Dr. D. Tait: We should not change our treatment of hip-joint disease on the history of a single case and especially when there is no convincing evidence that the case was really one of tuberculosis. The history sounds more like a case of osteomyelitis. The transtrochanteric route is not a new one for reaching the hip.

Dr. S. J. Hunkin: The case reported certainly sounds more like one of osteomyelitis than tuberculosis, and we can not draw any analogy between tuberculosis and infections with the pyogenic organisms. Dr. Sherman performed a somewhat similar operation to the one here advocated in 1894 before the American Medical Association and the patient is still under treatment with an abscess. He showeed 7 skiagraphs of hips mostly taken 5 to 6 weeks after the onset of symptoms, and in not one of them can a definite focus be made out. The joint looks simply somewhat blurred. Where would be the focus to attack? Furthermore the injury to the epiphysial line might result in very serious shortening of the leg. In operations on tuberculous ankle-joint disease he had found that even where the *x*-ray showed no joint involvement, there was yet granulation tissue, presumably tuberculous, present in the joint.

Dr. E. Rixford: As a matter of fact, we can rarely make a diagnosis of a limited focus in the head of the femur, and then remove it without infecting the joint. In the operation advocated by Dr. Huntington, the operator is working in a deep hole and it is doubtful if he can effectually remove all the diseased tissues, and make out the precise extent of the disease.

Dr. Ophuls: The granulation tissue of tubercular joints can be shown in most cases to contain tubercles, although it is more difficult to demonstrate the bacilli. For this a large number of serial sections is often necessary. In old, nearly healed cases, no tubercles may be found.

Dr. Huntington, in closing, said that it must be admitted that the evidence that the present case was of tubercular origin is not conclusive. The microscopic examination of the pus was negative and no inoculations were made. The case operated on by Dr. Sherman was not similar to the one here described, and indeed, just such treatment has rarely been attempted and little is known about it. The danger to the epiphysial cartilage is certainly present if no operation is performed, for it may be destroyed in the course of the disease. The periosteum can supply nutrition to the bone. Tubercular knees and ankles do not fall within the scope of the present paper.

Dr. Hunkin: There is no relation between the removal of the epiphysis by operation and its destruction by disease. In the latter case, for some unknown reason, the bone may retain its nutrition and may even grow excessively.

CLEVELAND ACADEMY OF MEDICINE.

Sixteenth Regular Meeting of the Clinical and Pathologic Section, held May 6, 1904.

Dr. Carl A. Hamann in the Chair.

Acute Dilatation of the Stomach Complicating an Abdominal Section.

Dr. Hunter Robb read a paper on this subject, and reported a case in which dilatation of the cervix and curettement of the uterus was performed and immediately followed by an abdominal section to remove an adherent appendix, resect a cystic ovary and suspend the uterus. On opening the abdominal cavity a large tumor presented which reached to the symphysis and proved to be the dilated stomach. The stomach tube was passed, a considerable amount of gas and some fluid escaped, and the organ at once returned to its normal size. The day after the operation the stomach became moderately distended, and the condition was again relieved by the stomach tube. From this time no further trouble was experienced.

Dr. Sawyer drew attention to the fact that the stomach was markedly under the control of the nervous system, and that dilatation may occur with startling suddenness. He mentioned a case of acute dilatation during typhoid fever following the swallowing of some beefsteak. The condition is often accompanied by shock, and some cases of shock during operation may be caused by this.

Dr. Hamann had seen reports of numerous cases, usually in abdominal operations, but also after others, such as renal operations; it may also cause a fatal result in infants.

Hydatidiform Disease.

A report of a case of this disease prepared by Dr. John B. McGee was read by the Secretary, in Dr. McGee's absence. According to Palmer Findley, only 210 cases of this disease had been recorded up to March, 1903. Nothing definite is known of its immediate or remote causes, nor is the question of its origin, whether fetal or maternal, fully settled. The mortality is about 25 per cent., and the disease usually occurs near the end of the childbearing period. About 16 per cent. become malignant. This patient, aged 37, had had 8 living children and no miscarriages. Two months after the cessation of menstruation due to this last pregnancy, she began to flow, and this continued irregularly and in small amount for four months, when it became profuse, and the uterus was emptied. At this time the uterus was as large as at term, but it was more smooth and rounded than usual and no fetal parts could be felt. The os was patulous, but there were no pains. As tamponade did not control the hemorrhage, the os was dilated and some of the vesicles removed, clearing up the diagnosis. The uterus was emptied and packed with iodoform gauze. No fetus could be discovered. The convalescence was uneventful. The following month menstruation appeared, and was regular until seven months ago, when the patient again became pregnant. The present gestation seems to be progressing normally.

Radium Cure of Lupus.

Dr. Myron Metzenbaum presented a case of lupus healed by the aid of radium. This patient had been treated for some time with the Roentgen rays, at first with marked improvement, but later this treatment seemed to lose its efficiency, and radium was tried with marked improvement After 21 days the surface was entirely healed, although Dr Metzenbaum said the permanency of the cure was of course not certain, and many months must elapse before the case can be considered healed Drs Corlett, Leuke and Birge discussed the paper

---

AMERICAN ACADEMY OF RAILWAY SURGEONS.

Joint Meeting of the International Association of Railway Surgeons and the American Academy of Railway Surgeons, held in Chicago, June 1, 2 and 3, 1904

During the first day the sessions were presided over by Dr. James H Ford, Indianapolis, president of the International Association of Railway Surgeons, and the sessions of the second and third days by Dr Samuel C Plummer, Chicago, president of the American Academy of Railway Surgeons

Welcome.

An address of welcome was delivered by Dr William A Evans, Chicago, which was responded to by Dr George Ross, Richmond, Va

Presidential Addresses.

President Ford discussed the "Use and Abuse of the Railway Surgeon" in his presidential address, and President Plummer selected as the subject of his address, "Following and Assisting Nature"

Merger and New Organization.

The following resolutions were introduced and adopted

Resolved, That at the close of the present session the International Association of Railway Surgeons dissolve its present organization for the purpose of organizing the American Association of Railway Surgeons provided that a union be made with the American Academy of Railway Surgeons at the meeting set for that purpose

Resolved, Further, That the Executive Board of this Association be authorized to join with the Executive Board of the American Academy of Railway Surgeons and organize the American Association of Railway Surgeons

Temporary Organization

The two associations having dissolved, Dr David S Fairchild, Des Moines, was elected temporary chairman, Dr Louis J Mitchell, Chicago, temporary secretary

Constitution and By-Laws

Dr. Albert I Bouffleur, Chicago, presented the report of a joint committee on constitution and by laws for governing the new organization, which was accepted and adopted

Election of Officers

The following are the officers of the consolidated organization—the American Academy of Railway Surgeons President, Dr John E Owens, Chicago, vice presidents, Drs Richard W Corwin, Pueblo, Colo, George D Ladd, Milwaukee, Wis, and Henry C Fairbrother, East St Louis, Ill, treasurer, Dr Thomas B Lacey, Council Bluffs, Iowa, secretary, Dr Henry B Jennings, Council Bluffs, Iowa, editor, Dr Louis J Mitchell, Chicago, executive board Drs David S Fairchild, Des Moines, Iowa, and Albert I Bouffleur, Chicago, three year term, Drs Samuel C Plummer, Chicago, and Arthur L Wright, Carroll, Iowa, two year term, and Drs William S Hoy, Wellston, Ohio, and Joseph R Hollowbush, Rock Island, Ill, one year term

---

Miscellany.

IMPROVED MEDICAL JURISPRUDENCE.

A Forward Movement in the Treatment of Certain Cases—A Case in Point.

BY DR D R BROWER, CHICAGO

Michael Curran, after several days of excessive indulgence in alcoholic stimulants, was found to be insane by the physician called to see him Under the impression that it might be a case of acute alcoholism, he was placed in the Washingtonian Home for treatment Here it soon became manifest that it was something more, and Dr Archibald Church was called in consultation, and made the diagnosis of general paresis

The patient was then tried by the court, adjudged insane, and last January was sent to the Lake Geneva Sanitarium. There he rapidly improved, the alcoholic effects disappeared, and his general health became better under vigorous alterative treatment, so that his friends supposed him well At the suggestion of these friends, and with the approval of his brother, Thomas Curran, the conservator, I was then sent to the sanitarium to determine the mental condition of the patient It did not require a prolonged interview to make a diagnosis of general paresis, all the classical signs of the disease being present, and a report was made accordingly The report did not satisfy these friends, and they instituted habeas corpus proceedings in the Circuit Court of Cook County, Judge Lockwood Honore presiding The medical experts, Drs Church, Stearns, Buford and myself, suggested that the court call to his assistance three physicians skilled in mental and nervous diseases to sit with him as amicus curiæ in the trial, that two of them be selected on the advice of his family physician, and these two to select a third The court accepted the suggestion The result was the trial of the case by a jury of three eminent specialists, Drs Sanger Brown, Sidney Kuh and Hugh T Patrick This was a thoroughly dignified and scientific proceeding, one that I think should appeal to courts generally in similar cases The opinion of the court follows·

State of Illinois, County of Cook, ss In the Circuit Court of Cook County
In the matter of Michael Curran Petition for writ of habeas corpus

OPINION OF THE COURT

The Court—Before the hearing of this case was begun it was agreed between counsel on both sides that inasmuch as the question to be determined was largely a matter for expert opinion, the court might, at the expense of the parties, call to his assistance in arriving at a conclusion three practitioners eminent in their profession, as experts on the questions involved in this case and it was further agreed between counsel representing the friends of Michael Curran, and counsel representing the respondent that the opinion which should be rendered by said three experts should be conclusive in the case

The court thereon requested the assistance of Dr Sanger Brown, Dr Sydney Kuh and Dr Hugh T Patrick

These three gentlemen heard all of the evidence which was adduced on both sides, and at the conclusion thereof made a personal examination of the relator in his own apartments, lasting two hours, as a result of which they have handed to the court the following opinion

"Chicago, May 11, 1904

To the Honorable Lockwood Honore, Judge of the Circuit Court

'*Sir*—Pursuant to your request, we have listened to all of the evidence submitted in court in the case of Michael Curran, and have also carefully examined him as regards his physical and mental condition This examination was made jointly in the absence of all other persons and occupied two hours We now have the honor to submit the following unanimous opinion based on the evidence and on our personal investigation of the patient

"In our opinion the said Michael Curran is now (and has for at least four months been) suffering from the disease called general paresis, paretic dementia and general paralysis of the insane This is a form of mental failure due to organic changes in the brain and is incurable Ordinarily the disease runs its course to a fatal termination within three years from the appearance of positive symptoms

We further believe that the said Michael Curran is not irresponsible for his acts but is quite incapacitated for the ordinary care of his health his safety and his business affairs While general paresis is not one of the forms of insanity most dangerous to others, nevertheless a person with this disease is liable to sudden outbursts of passionate anger from trivial cause and in such state of passion is certainly dangerous

'Therefore, we believe that the said Michael Curran should be in the care of a proper conservator who may shield him and save him in every possible way from the disastrous effects of his disease

"Considering that general paresis is frequently not recognized by the laity, even by intelligent friends in daily contact with the patient until the disease has progressed to a most alarming extent or until some great disaster overwhelms the victim, we beg to respectfully add some specific details and general considerations bearing on the present condition of Michael Curran, and on the probabilities of his immediate future And in this connection we beg to make the reminder that the daily task of the physician is not only to determine the present condition of the patient and prescribe the treatment but equally, to look ahead and anticipate future events and provide for them Knowing the nature of a tumor he is able to say that it will never shorten the life of the patient or that it will soon lead to the end Though no pain be present, he knows that pain will soon come Fever may be slight and the skin clear The doctor must know that in a few days the temperature will be high and the body covered with rash This ability to anticipate applies to mental as to other diseases though perhaps not with the same exactitude and enables us to safeguard the patient for the future, even though he may show but slight abnormality at present

"First, then Michael Curran shows no just appreciation of the gravity of his symptoms and the seriousness of these legal proceedings Though his life his liberty and his property are all involved in this inquiry, he is happy serene, inconsequential. He is absolutely untouched by the serious and repeated assertions of four reputable physicians that he has an incurable disease. True, he wishes his liberty, but the fact that he may for the rest of his natural life be sequestered in an institution for the insane really gives him no concern. When, in the course of our examination, he was unable to make change in the simplest sums, he was entirely undisturbed. When, after repeated corrections, he could not tell how much twenty-five cents and fifteen cents would be, and when with pencil and paper he could not figure out how much the half of $65 would be, he saw absolutely no significance in the failures. Be it remembered that these were computations of his daily life which he had done with ease and accuracy for many years.

"Furthermore, during the hearing and during our examination when talking about the testimony, he evinced no active interest in the statements of the witnesses, showed absolutely no concern regarding serious statements involving life, liberty and property, not only was he unable to understand the significance of much that was said, but was quite indifferent to what he did understand. His own conduct during the hearing may well be contrasted with that of his brothers and his friends, for all of whom the proceedings were naturally of infinitely less concern than for him.

"The testimony and our own examinations shows clearly to us mental failure, both as regards memory, judgment and the general appreciation of his surroundings and of events concerning himself. Beginning with the matters which concerned him most frequently and with which he was naturally most familiar and mental operations which he had so often repeated that they must have become almost automatic, we may state that during our examination, when asked how much the bill would be for three drinks of whisky at 15 cents each, he said that there would be two for a quarter and 15 cents for the other, but repeatedly and after being told a number of times that his statement was incorrect, he asserted that the amount was 35 cents. During this computation he became so confused that he sometimes added 10 cents to the 25, sometimes 15, but continued to make the sum 35 cents. With pencil and paper he correctly multiplied 65 cents by 5, the proposition being the cost of 65 barrels of beer at $5 a barrel, but was unable to estimate his rebate, which was 50 cents a barrel. This he attempted to do with pencil and paper, but was absolutely unable to do it, saying first that it would be $22.50 and then $17.50, then $30, and finally, after great effort and obvious confusion, did hit on the correct sum. When asked how much would remain if $2.35 were taken from $10 he was entirely unable to state the remainder, and then when he made the attempt with pencil and paper, made numerous errors and had to be corrected several times before arriving at the correct amount.

"In order to make these tests as fair and realistic as possible, w procured a lot of small change and made dummy purchases of him, as it were, over a bar. The first proposition was to pay a bill of $2.60, for which he was handed a $10 bill. It was with great difficulty and extreme slowness that he finally counted out change, which was wrong by 90 cents. When he was told that this was wrong and did it over again, he again made an error, but finally gave correct change. He was then asked to take $3.75 out of $10 and this time he gave the correct change, but it was only after the expenditure of a great amount of time, after counting and recounting and making numerous mistakes. There were other similar tests, but the foregoing are fair examples. These were all made after it was explained to Mr. Curran what their purpose was, and that it was to give him an opportunity to make good his assertion that he was amply able to make change and do all computations necessary for the transaction of his business. We also made the attempt to have him as much at ease as possible, asked him to take plenty of time, and it is fair to suppose that he was exercising his intellect to the utmost of his ability.

"We think it also worthy of remark that he had no recollection whatsoever that more than one physician was called on his side, who had examined him and testified in his behalf. He could recall really none of the essential features of any of the testimony either for or against him, except in a general way that his friends thought he was all right and the others that there was something the matter with him.

"Furthermore, Mr. Curran showed lack of appreciation of the fact that he was in an abnormal condition about the time of Christmas of last year when he was sent to the Washingtonian Home, to the Detention Hospital, was adjudged insane and sent to Lake Geneva. Not only is he unwilling to admit that he was not all right at that time, but he is certainly sincere in his belief that he was at first only slightly under the influence of liquor, and that after the fi day he was simply 'a little nervous.' The testimony of every witness who testified concerning his condition at that time, excepting that of Mrs. Morgan, was to the effect that there were then exceedingly obvious symptoms of mental disturbance. Had the disturbance at that time been simply the result of a spree, and were Mr. Curran at present normal, his view of his then condition would be decidedly different from what it is at present. He would recognize now that he was at that time in an abnormal condition.

"The physical examination, made with the patient completely stripped and which was thorough in every respect, revealed to us the ordinary classical and universally recognized signs of general paresis. The state of the pupils, the disorder of speech, the condition of the deep reflexes, the character of the tremor present, and the disturbance of co-ordination, made a group of symptoms which would be absolutely conclusive to anyone conversant with the disease.

"As stated in the beginning of this report, we are firmly convinced that should Mr. Curran be released and allowed to do as he pleases, to gratify his appetites, whims and desires without restraint, that he would not only hasten the course of his disease to a fatal termination, but would inevitably bring calamity of some sort on himself if not on others. With his exceeding confidence in himself and his powers, his ever-present feeling of good-fellowship and liberality, and with practically no power of self-restraint, even if he saw the necessity for it, he is sure to overindulge in alcohol and to be injured by other excesses. Judging by our experience with like cases, we believe that in the conduct of his business he would be not only extravagant but irrational, would very readily be induced to enter into calamitous contracts, because unable to appreciate the significance of such transactions. The danger of violence to others has already been noted, and while we believe such danger to be not very imminent, it is always to be reckoned with. The danger of suicide and of the commitment of a criminal act are also more than mere possibilities. We have all had examples in our own practice of patients with general paresis who, although apparently perfectly harmless and, indeed, more nearly normal than Mr. Curran, have suddenly and without warning committed suicide, made dangerous assaults on others, or committed some other criminal act.

"Consequently, we are firmly convinced that for the sake of his own health, comfort, welfare and safety, as well as for the protection and welfare of the public and the conservation of his property, he should remain in restraint. Our experience leads us to believe that it would be impracticable and injurious to Mr. Curran to allow him to be at large in the custody of an attendant. We also believe that travel with such attendant would be of no benefit to him and might result in great difficulties and serious harm.

(Signed)

"SANGER BROWN,
"SYDNEY KUH,
"HUGH T. PATRICK."

In view of the foregoing, there seems to the court no other alternative than to follow the opinion and the recommendations above made.

The relator will, therefore, be remanded to the custody in which the writ found him. The petition will be dismissed and the writ quashed.

Book Notices.

THE INTERNATIONAL MEDICAL ANNUAL. A Year Book of Treatment and Practitioner's Index. 1904. Twenty-second Year. Cloth. Pp. 770. Price, $3.00 net. New York: E. B. Treat & Co.

This work is intended as a general epitome of the more striking advances in medicine during the year prior to its publication. That it has acceptably fulfilled this function is shown by the fact of its having entered on its twenty-first year. The articles and abstracts are made up by skilled collaborators of more than local reputation, and the general practitioner will find it a valuable résumé—one that will enable him to collect his views and recollections of the publications of the preceding year.

THE LYMPATHICS. General Anatomy of the Lymphatics, by G. Delamere. Special Study of the Lympathics in Different Parts of the Body, by P. Poirier, Professeur d'Anatomie a la Faculté de Médecine a Paris, Chirurgien des Hôpitaux, and B. Cunéo, Professeur agrégé a la Faculté de Médecine de Paris. Authorized English Edition by Cecil H. Leaf, M.A., M.B. (Cantab.) F.R.C.S. (Eng.), Assistant Surgeon to the Cancer Hospital. With 117 Illustrations and Diagrams. Cloth. Pp. 301. Price, $5.00 net. Chicago: W. T. Keener & Co. 1903.

This work is divided into two parts; the first, of 110 pages, treats of the "General Anatomy of the Lymphatic System," and part two, of about 200 pages, is devoted to the "Special Study of the Lymphatics of the Body." In part one, the leucocyte in all its varieties and forms is very extensively and interestingly considered. The structure, the physical, chemical and biologic properties and the evolution (degeneration and death) of the leucocyte are studied in a most entertaining manner. The lymphatic vessels and glands are then described in the same careful way. A thorough knowledge of the location of the lymph glands and of the area tributary to each gland or group of glands is often of the greatest importance, not only to the surgeon in operating, but also to the diagnostician. These points are all well described and clearly illustrated in part two. An extensive and well selected bibliography follows each subject. The work is an excellent one, and shows an immense amount of careful, painstaking labor on the part of the authors, The translation is well done, and the profession is to be congratulated that it is able to obtain the work in English.

ATLAS AND EPITOME OF HUMAN HISTOLOGY AND MICROSCOPIC ANATOMY. By Dr. Johannes Sobotta, of the University of Würzburg, Bavaria. Edited, with additions, by G. Carl Huber, M.D., Junior Professor of Anatomy and Director of the Histologic Laboratory at the University of Michigan. Authorized Translation from the German. With 171 Illustrations on 80 Lithographic Plates, and 68 Text Illustrations. Cloth. Pp. 248. Price, $4.50 net. Philadelphia and London: W. B. Saunders & Co. 1903.

This little atlas is one of the most valuable for the medical student that has yet appeared. In the first place it deals distinctively with human tissues, and in the second place the plates are nearly all reproduced in the exact colors that are taken by tissues stained with hematoxylin and eosin. There is no question that it is of great assistance to a student to have the illustrations in his text in the same colors as are the sections he is studying under the microscope, and hematoxylin and eosin staining is the method in common use. The text, although necessarily brief, is excellently written and quite accurate, better, we think, than in many of the larger books that can not claim so much for their illustrations. There are a few unfortunate omissions, not all of which are necessitated by the brevity of the book. For example, the illustration of the pancreas shows none of the islands of Langerhans, a serious defect in a book to be used by medical men. Illustrations of the parathyroid glands, the hypophysis, and the hemolymph glands would have also been useful in the same instance. But the numerous and more important illustrations present are both accurate and pleasing to a high degree.

A Text-Book of Diseases of Women. By Thomas A. Ashby, M.D., Professor of Diseases of Women in the University of Maryland. With 233 Illustrations. Cloth. Pp. 661. Price, $4.50. Baltimore: Williams & Wilkins Co. 1903.

The author states that "In a concise and practical way he has tried to present all of the subjects embraced in a study of the diseases of women." After a brief historical sketch the anatomy and development of the parts are considered. Most of the illustrations in this connection are satisfactory, but Figure 5, representing the perineal body, grossly exaggerates that structure so as to give one an entirely erroneous idea concerning it. Figure 23, illustrating the nerves of the uterus, is taken from Bardeleben's Anatomy and shows a pregnant uterus, neither of which facts is mentioned. Chapters on methods of examination and technic are fair. The pathology throughout the work is not up to date, and no one would ever recognize tubercle bacilli from the illustration on page 218. The statements that the gonococcus "invariably finds its way into the vagina through impure sexual intercourse" and that "gonorrheal endometritis is seldom observed except among immoral women" are not in accord with the experience of other observers. At times the directions for treatment are very indefinite, for instance, on page 500, we find, "In old and long-standing cases of ectopic pregnancy where the child has been converted into a lithopedion or has become mummified, etc., the child should be left alone for nature to dispose of its remains or the surgeon should assist Nature in the effort at its elimination by such measures as will favor this result," but nothing whatever is said of what measures might favor such a result. The closing chapter is devoted to intestinal complications and methods of intestinal suture. As a whole, the work covers fairly well the subject of gynecology, but it can not be said to possess any qualities or marks of distinction.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Acne.

In the treatment of acne of the face, the "blackheads" must first be expressed out by the small instrument used for the purpose. To soften the skin and aid the procedure the parts should be washed with water as hot as can be borne, medicated with an alkali, like sodium or potassium carbonate in 5 to 10 per cent. strength; sodium bicarbonate 5 per cent.; ammonium chlorid 5 to 20 per cent., or sodium borate 5 per cent.

If more energetic remedies are desired, soaps medicated with resorcin or naphthol are of service. A combination similar to the following is also valuable:

℞.	Sulphuris precip.	ʒiiss	10
	Resorcini	gr. lxxv	5
	Zinci oxidi	℥ss	15
	Adipis lanæ	ʒv	20
	Liq. petrolati	℥i	30

M. Ft. unguentum. Sig.: Apply locally.

Similar combinations containing naphthol, salicylic acid or ichthyol may be used. The skin should be sterilized with alcoholic lotions containing mercuric bichlorid ½ to 2 per cent., or resorcin 5 to 15 per cent., to be applied at bedtime on cotton lightly soaked in the solution.

The following may be suggested for this purpose.

℞.	Resorcini	ʒi	4
	Aq. cologne	Oi	500

M. Sig.: Apply locally on cotton.

These solutions tend to prevent pustulation to some extent. At the same time constipation should be corrected, avoiding pastries and seasoned foods. In neurotic cases hydrotherapy is indicated.

In the pustular variety of acne, sulphur lotions are indicated, as in the following combination:

℞.	Sulphuris precip.	ʒvi	24
	Spts. camphoræ	℥ii	60
	Aquæ rosæ	℥viss	200
	Aq. destil.	℥vii	210

M. Sig.: Shake and apply at night with a brush and wash off with hot water the next morning.

If the pustules are not conspicuous, as on the neck or back, they may be painted with the tincture of iodin, which will in most cases arrest the inflammatory process. On the face a saturated solution of boric acid in alcohol may be used.

Internally the author recommends brewer's yeast in doses of one to two teaspoonfuls before each meal. Furunculous or phlegmonous acne sometimes requires surgical intervention with a fine scarifier.

Internally the vasoconstrictors are beneficial:

℞.	Ergotin		
	Quin. hydrobrom., āā	gr. i	06
	Ext. hamamelidis flu.	m. ii	12
	Pulv. belladonnæ fol.	gr. 1/12	005

M. Ft. pilula No. i. Sig.: Four such pills daily after eating.

Pourdon, in *Dublin Jour. Med. Science*, recommends the following in the treatment of acne:

℞.	Cadini iodidi	gr. x	65
	Adipis lanæ	℥i	30

M. Sig.: To be applied locally at night and well rubbed in and washed off the following morning with hot water and superfatted soap, accompanied by massage of all the affected skin.

Gastric Catarrh.

In cases of chronic gastritis, accompanied by pyrosis, the following is recommended in Yeo's *Clin. Ther.*:

℞.	Bismuthi subnit.	gr. lxxx	5
	Morphinæ hydrochlor.	gr. 3/4	05
	Sodii bicarb.	gr. xxx	2

M. Ft. chart. No. x. Sig.: One powder to be taken every two hours.

If there is loss of appetite the following:

℞.	Ext. gentianæ	gr. xxx	2
	Syr. aurantii corticis	ʒv	20
	Aq. destil. q. s. ad	℥vi	180

M. Ft. mistura. Sig.: One tablespoonful before each meal; or:

℞.	Tinct. nucis vom.	m. xxx	2
	Aq. *laurocerasi*	ʒiiss	10
	Tinct. quassiæ q. s. ad	℥i	30

M. Ft. mistura. Sig.: Fifteen drops to be taken, in water, three times a day.

For acute cases of gastric catarrh the following is recommended by the author:

℞.	Acidi carbol.	gr. ¼	015
	Bismuthi subnit.	gr. x	65
	Mucilaginis acaciæ	ʒss	2
	Aq. menth. pip. q. s. ad	ʒii	8

M. Sig.: To be taken in a tablespoonful of water every one, two or three hours.

In acute attacks of gastritis in infants, accompanied by nausea and vomiting, the following is recommended:

℞.	Acidi tartarici	gr. xv	1
	Aquæ laurocerasi	gtt. x-xx	.65-1 30
	Aq. destil. q. s. ad	℥v	150

M. Ft. mistura. Sig.: One dessertspoonful every two hours.

If fever is present the following is recommended:

℞.	Acidi hydrochlor. dil.	m. v-x	30-.65
	Syr. simplicis	ʒii	8
	Aquæ destil. q. s. ad	℥iii	90

M. Sig.: One dessertspoonful every two hours, in water. And if gastric irritability has disappeared but fever still remains, the following is suggested:

℞.	Quin. hydrochloridi	gr. v		30
	Acidi hydrochlor. dil.	m. v		30
	Syr. simplicis	℥iss	45	
	Aquæ destil. q. s. ad	℥iii	90	

M. Sig.: One teaspoonful every two hours.

Angina Pectoris.

Professor Huchard, in *Med. Press*, states the importance of distinguishing between true and false angina before instituting treatment. The latter gets well by suppressing the cause that provokes it—hysteria, neurasthenia, gastric troubles, over-indulgence in tobacco. But in true angina pectoris it is of but little use to treat the causal affection—gout, diabetes, syphilis, malaria—for the result is always negative. Consequently, according to Professor Huchard, it is not the pathologic cause that should receive attention, but the anatomic cause, viz., disease of the coronary artery. A double medication is, therefore, necessary; one addressed to the inflammation of the arteries, the other to the threatening syncope. Sodium or potassium iodid (the latter being more active if well borne) may be given as follows, and will meet the first indication:

℞.	Sodii vel. pot. iodidi	ʒi	4
	Aquæ	℥x	300

M. Sig.: One tablespoonful three times a day.

Against the danger of syncope vasodilators are prescribed. Previous to beginning the medical treatment attention should be given to the diet, which should be lacto-vegetarian and without salt as much as possible. As to the remedies given along with the iodids he gives theobromin as being one of the best diuretics. It eliminates the chlorid of sodium, the toxins and the vasoconstrictive substance from the organism. Ten grains are recommended at a dose, twice a day for fifteen days. Nitroglycerin is given in solution, in tablet form or hypodermically. In solution it may be prescribed as follows:

℞.	Sol. nitroglycerini (1 per cent.)	ʒi	4
	Aquæ	℥x	300

M. Sig.: Two to four tablespoonfuls a day.

This preparation, like other vasodilators, not infrequently provokes violent headaches. In such instances the dose should be diminished gradually, and not give a dose too weak to be of benefit.

As a substitute for the nitroglycerin, M. Huchard recommends the following containing sodium nitrite combined as follows with other diuretics:

℞.	Sodii nitritis	gr. xv	1
	Pot. nitratis	ʒii	8
	Pot. bicarb.	ʒiv	15
	Aquæ q. s. ad	℥vi	180

M. Sig.: One tablespoonful each morning. The extract of cactus grandiflora in one-grain pills three times a day is an excellent cardiac tonic.

When the heart shows signs of weakness digitalin given in solution—ten drops (.65) of a 1-1,000 solution of crystallized digitalin once a day for five days is of service.

When an attack comes on suddenly, amyl nitrite is the preparation to give to relieve the patient. As to general treatment the patient is warned against violent exercise, constipation, long walks against the wind or after meals.

Appendicitis.

Jonescu, in *Ther. Review*, states as his opinion, after many years of experience, that all cases of appendicitis should be treated medicinally in the beginning. His treatment consists of absolute rest in bed, extract opii ¾ to 1½ grains (.05-.10) daily, ice to the abdomen, starvation diet, large amounts of normal saline solution given subcutaneously or intravenously, and lavage in cases of persistent vomiting. Surgical interference is recommended by the author only after the initial peritoneal symptoms have abated, whether the condition has localized itself with or without abscess formation. The search for the appendix should not be carried too far, and its removal performed only when it is easily found. Intestinal fistulæ, which may remain after the operation, should be left to themselves as they usually heal spontaneously.

Burns of the First Degree.

The following combinations are recommended in an abstract in N. Y. Med. *Jour.* for burns:

℞.	Thymol	gr. ix		60
	Olei lini	℥iv	120	
	Sodii bicarb.	℥ii	60	
	Aquæ calcis	℥iv	120	

M. Sig.: Shake well and anoint the burnt surfaces thoroughly and cover with absorbent cotton; or:

℞.	Ext. opii	gr. ivss		25
	Ichthyol			
	Lanolini			
	Liq. petrolati, āā	ʒiii	12	

M. Ft. unguentum. Sig.: Apply locally.

Erysipelas.

Dr. A. Herzfeld, in *Critic and Guide*, after stating his experience in the treatment of erysipelas with alcohol, unguentum hydrargyri, the iodin treatment in the form of the tincture of iodin and the compound iodin ointment, unguentum Credé and carbolized vaselin, recommends the following outline of treatment as the best to be employed in the treatment of this affection: The affected surface is first washed with pure alcohol, after which an ice cold, diluted solution of plumbi subacetate to which tincture of opium has been added in the proportion of one ounce (30.) to a pint (500.), is constantly applied. The affected surface is kept constantly moist by these applications, which have the advantage of relieving the pain considerably. If large amount of the foregoing preparations should be required, as in dispensary work, the following formula is recommended:

℞.	Liq. plumbi subacetat.		
	Tinct. opii, āā	℥viii-xvi	250.-500

M. Sig.: Two tablespoonfuls to a pint of water and applied locally.

After the acute symptoms have subsided, ichthyol is applied to the affected surface in the form of an ointment as follows:

℞.	Ichthyoli	ʒiv-℥ii	15.-60
	Adipis lanæ	℥v	150

M. Ft. unguentum. Sig.: Apply locally.

The author prefers wool fat as the basis of an ointment because it is neutral in reaction, it does not contain any fatty acid, nor any compound which will produce a fatty acid; allows an easy and rapid penetration of the medicine through the skin, and is not readily affected by chemical change. The older ointment bases, such as adeps, unguentum simplex, vaselin and oleates, often irritate the skin and absorption takes place rather slowly. In the internal treatment of erysipelas, salol, in powder form, has been of best service to the writer. In severe cases the use of stimulants for cardiac depression may be required, hydrotherapy for hyperpyrexia, while necrosis and suppuration may require surgical interference.

Smolitcheff, in *Med. Rev. of Reviews*, recommends the following combination in the treatment of erysipelas:

℞.	Tinct. iodi	ʒvi	24
	Olei camphoræ		
	Ichthyoli, āā	ʒiii	12

M. Sig.: Shake well. Apply locally two or three times daily.

The following combination locally has been recommended in local treatment of erysipelas:

℞.	Acidi tannici	gr. xxx	2
	Pulv. camphoræ	ʒi	4
	Spts. etheris	ʒv	20

M. Sig.: To be painted over the affected area every hour or two.

Aristol is also a good antiseptic applied in the following manner:

℞.	Aristol	gr. xv	1
	Collodii	℥i	30

M. Sig.: Paint freely over the affected area with a camel's hair brush, covering a small portion of the surrounding healthy skin.

Medicolegal.

Duty to Provide Proper Medical Treatment for Seamen.—The Supreme Court of the United States affirms the judgment in the case of the *Iroquois*, reported on page 467 of THE JOURNAL of Feb. 14, 1903, holding it to have been the duty of the master to put into an intermediate port for surgical aid for a seaman injured, who fractured two ribs and his right leg in two places by a fall. It says that the duty to provide proper medical treatment and attendance for seamen falling ill or suffering injury in the service of the ship has been imposed on the ship owners by all maritime nations. It appears in the earliest codes of continental Europe and was expressly recognized by this court in the recent case of the *Osceola*, 189, U. S. 158. On large passenger steamers a physician or surgeon is always employed, whose duty it is to minister to the passengers and crew in cases of sickness or accident. Of course, this would be impracticable on an ordinary freighting vessel, where the master is presumed to have some knowledge of the treatment of diseases, and in ordinary cases stands in the place of a physician or surgeon (the *Wensleydale*, 41 Fed. Rep. 602), but for the further protection of seamen, vessels of the class of the *Iroquois* are compelled by law to be provided with a chest of medicines and with such anti-scorbutics, clothing and slop chests as the climate, particular trade, and the length of the voyage may require. U. S. Revised Statutes, sections 4569, 4572, 4573. What is the measure of the master's obligation in cases where the seaman is severely injured while the ship is at sea has been made the subject of discussion in several cases, but each depends so largely on its own peculiar facts that the rule laid down in one may afford little or no aid in determining another, depending on a different state of facts. The early cases of Harden vs. Gordon, 2 Mason, 541, and Reed vs. Canfield, 1 Sumn. 195, contain an exhaustive discussion of the general subject by Mr. Justice Story. We can not say that in every instance where a serious accident occurs the master is bound to disregard every other consideration and put into the nearest port, though if the accident happen within a reasonable distance of such port, his duty to do so would be manifest. Each case must depend on its own circumstances, having reference to the seriousness of the injury, the care that can be given the sailor on shipboard, the proximity of an intermediate port, the consequences of delay to the interests of the ship owner, the direction of the wind, and the probability of its continuing in the same direction, and the fact whether a surgeon is likely to be found with competent skill to take charge of the case. With reference to putting into port, all that can be demanded of the master is the exercise of reasonable judgment and the ordinary acquaintance of a seaman with the geography and resources of the country. He is not absolutely bound to put into such port if the cargo be such as would be seriously injured by the delay. Even the claims of humanity must be weighed in a balance with the loss that would probably occur to the owners of the ship and cargo. A seafaring life is a dangerous one, accidents of this kind are peculiarly liable to occur, and the general principle of law that a person entering a dangerous employment is regarded as assuming the ordinary risks of such employment is peculiarly applicable to the case of seamen. To judge of the propriety of the master's conduct in a particular case we are bound, so far as possible, to put ourselves in his place, and inquire whether, in view of all the circumstances, he was bound to put into an intermediate port. The court lays no stress on the fact that the seaman in question did not ask to be taken into an intermediate port. He was a boy, largely ignorant of his rights and duties. The master was his legal guardian in the sense that it is a part of his duty to look out for the safety and care of his seamen whether they make a distinct request for it or not.

Absent Treatment and the United States Postal Law.—In the case of the United States vs. Post, tried in the United States District Court, Southern District of Florida, there were four indictments under the law, which provides, in substance, that, "if any person, having devised any scheme to defraud, to be effected by opening or intending to open correspondence through the United States mail, shall, for executing such scheme, deliver any letter, book, writing, circular, pamphlet, or advertisement in any postoffice of the United States, he shall upon conviction, be punished." The first three indictments charged, in substance, that the defendant had devised a scheme to defraud, which consisted, as was fully set forth, of making false and fraudulent representations as to her ability and power to cure persons by a so called "absent treatment," without intending to give such treatment, or to cure persons, as she had promised to do. The fourth indictment charged that the offense consisted more especially in promising to cure third persons without their knowledge, or without direct influence on them, by treating through an intermediate person, and that she could not so cure them, and that she knew she could not, and that she did not intend to cure patients by such treatment. The foundation of the contention of the government was that what was promised to be done could not have been intended, because the fulfillment was known to be impossible by the means proposed by the defendant, viz., the transfer of the power of her thought to the person of the patient with a curing influence sufficient to accomplish the changes in condition that were declared could be accomplished, and particularly in the cases of treating a third person unawares of such contemplated treatment through a second party. The contention of the defendant was that what she had promised was to be performed by the discovery of a new law of mental healing, by which healing thoughts could be sent out for the purpose of cure. The law of the case is contained in the charge of District Judge Locke to the jury, in which he stated, among other things, that there are well settled and accepted natural laws, a recognition of which is justified by the long experience of men, the knowledge of everyday life as well as by the studies and experiments of ages. Of these we may take cognizance—the laws of gravitation, cohesion, of optics, the phenomena of electricity, etc. But when one contends that he has made new discoveries in science or art, opposed to the general experience of man for ages, and directly in conflict with the generally accepted rules, and seeks to gain money or secure profit thereby, the burden of the proof of the truth of such discovery is on the party making the claim, and the truth of such contention must be satisfactorily proved before it can be accepted. As to the contention of the defendant, through all of her published works, that she could actually send, by emanations from her own mind, such power as would, after passing through the mind of a second person, influence the physical condition of a third person, which power it was further claimed could be taught to any class in a four weeks' course, the judge declared that he had no hesitation in saying that this power was not recognized as a natural law by the experience of mankind, and that she was attempting to establish a new and unrecognized law of nature, and therefore the burden rested on her to satisfy the jury that she possessed such power, and could do what she promised and advertised to do. Where testimony is directly contrary and in opposition to the well established laws of nature, accepted by all men from the experience and study of ages, such testimony may be properly ignored without contradiction. So the testimony of several parties that they had been treated by the defendant and cured, it appearing that they were at the time great distances from her, and totally ignorant of her acts and doings at the time, was so contrary to the well established rules of evidence and natural laws that it could not be accepted as stated. Furthermore, if any phenomena or pretended result of any new idea or new discovery in science which is contrary to nature as recognized can be explained and accounted for on natural principles and known laws, rather than by those which are in opposition to such, the natural explanation should be accepted, and such phenomena or results rejected as evidence of the pretended discovery. Therefore, if the jury should believe from the evidence that the cures or improvement of the patients so testified to might have resulted from the hopeful condition of their own mind, although suggested by the letters from the clerks of the defendant, or from any natural limitation or course of the disease, and not from any thoughts emanating from the mind of the defendant, the jury were not bound to accept such evidence as sustaining the contention of the defendant. Again, the judge said that the knowledge of the party at the time of making a promise or holding out an inducement for profit or gain is a good test of the intent of the party making it. No sane person of reasonable judgment can be considered as intending to do that which he at the time knows is and will be impossible for him to do. Therefore, if it was found that at the time the defendant promised, as was charged, that she could and would cure as she said she would, she knew she could not so cure, her intelligence might be inquired into to determine whether or not she intended to give treatment or any other equivalent for what she had promised. What the verdict was is not stated in the report of the case.

1 *Conservative Treatment of Acute Appendicitis. A. W. Morton.
2 Leishman-Donovan Blood Parasites (a Synopsis). Joseph McFarland.
3 *Varicocele. Henry D. Furniss.
4 *Results of the Roentgen Method in the Diagnosis of Renal Calculus. Charles Lester Leonard.
5 *Neuroses of Nasal Origin. G. Hudson-Makuen.
6 Importance of a Correct Diagnosis in the Treatment of Diseases of the Stomach, with a Summary of 30 Consecutive Cases. Albert Woldert.
7 *Influence of Old Age, Diabetes, Arterial Sclerosis and Gout on the Healing of Wounds. Wells P. Eagleton.
8 The Care of the Insane. W. J. Howells.

1. **Conservative Treatment of Acute Appendicitis.**—Morton favors Ochsner's method of treating the acute attack by rest, and believes that all of the cases can be carried through and patients operated on in the interval.

3. **Varicocele.**—Furniss describes the condition and advises conservatism in ordinary cases where serious symptoms and discomfort are not produced. The operation itself is not entirely a safe one, and is more dangerous than generally supposed, as is shown by illustrative cases. Asepsis should be as complete as possible. Greater care is required in asepsis here than in some apparently more serious operations. We should operate with as little trauma as possible and be careful not to injure the vas, the blood supply, the testicle, epididymis, etc. Subcutaneous ligation of the veins is objectionable, for a vein may be isolated under the impression that it is the vas and the vas be ligated for a vein. The swelling is also greater than with the open method. A small vessel may be punctured, giving rise to a bleeding that may necessitate incision and evacuation with ligation of the bleeding point, furnishing admirable culture media for germs. The open operation is the one of choice, and a high incision is better than one through the scrotum. He describes the method as given by Kocher in the fourth edition of the "Chirurgische Operationslehre." It consists in incising above Poupart's ligament, separating the cord and veins with resection, after the isolation of one to three inches of the veins. The veins are ligated with a No. 2 plain catgut in two places, and the distance between is proportionate to the amount to be resected. After resection the ends are united by tying the ligatures, which have been left long for the purpose, and with one or two stitches. All the bleeding points should be controlled by ligatures. The wound should be closed with a subcutaneous suture of plain catgut and dry sterile gauze dressings applied. An important point is the supporting of the scrotum while the patient is in bed with a suspension bandage and perfect asepsis.

4. **Renal Calculi.**—The value of the Roentgen ray in the diagnosis of renal calculi is pointed out by Leonard, though he does not advise entire dependence on it.

5. **Neuroses of Nasal Origin.**—Makuen briefly refers to a number of forms of neuroses relieved by nasal operations, and holds that it is reasonable to suppose, though not absolutely proven, that some of the more serious mental and cerebral diseases may be of nasal origin. Many so-called reflex nasal neuroses may be so explained on the theory of faulty respiration and impaired cerebral circulation due to direct intranasal pressure and the absorption of toxic catarrhal products through the blood and lymph. A careful examination of the nose is imperative in all doubtful cases of nervous disease.

7. **Healing of Wounds.**—Eagleton discusses the influence of old age, diabetes, etc., on the healing of wounds. He thinks the essential consideration in operating on old people, aside from damaged kidneys, heart, etc., is to guard against shock. This being eliminated, union may be as rapid as in younger patients. As to diabetes, the danger is from the low vitality of the tissues and the special liability to infection which is aided by the arteriosclerosis so frequently associated. We should remember the frequent association of this arteriosclerosis, and interfere as little as possible with the blood supply, keeping in mind the special liability of the tissues to infection, their low vitality and the danger of nerve degeneration, avoiding the possibility of even slight pressure over the site of operation.

9 *A Study of Certain Cases of Sarcoma of the Long Bones from the Massachusetts General Hospital Clinic. Charles L. Scudder.
10 *Disinfection of the Clinical Thermometer. Francis P. Denny.

9. **Sarcoma of the Long Bones.**—Scudder analyzes 15 cases of sarcoma of the long bones treated in the Massachusetts General Hospital, where the history could be obtained. He does not speak positively as to cured cases, for metastases may occur even after five years, but there have been two cases at least of 6 and 15 years' freedom from disease in cases operated on for giant-celled sarcomata. He points out the lesser malignity of the giant-celled than the round- or spindle-celled form, and discusses the propriety of excision in these cases rather than amputation. He thinks it may be advisable in very carefully selected cases and only in such. A detailed report of cases concludes the paper.

10. **Thermometer Disinfection.**—The method advocated by Denny is that of inserting a wad of cotton with a few drops of formalin in the end of the thermometer case as a disinfectant, and he gives the result of experiments and controls. In the 25 tests made with diplococcus, staphylococcus, typhoid bacillus, etc., there were no results in any instance, though in some cases the formalin had been put in the case a number of weeks prior to the test. All the controls showed growth. He thinks the convenience as well as the efficacy of this method should insure its more general use by the practitioner.

11 Some Considerations on Infection and Immunity. Thomas E. Satterthwaite.
12 *Notes on the Epidemic of Cerebrospinal Meningitis. Henry D. Chapin.
13 *Clinical Features of Cerebrospinal Meningitis, or Cerebrospinal Fever of the Epidemic Type. Henry Koplik.
14 A Plea for the Organization of a "Society of Sanitary and Moral Prophylaxis." Prince A. Morrow.
15 Management of Occipitoposterior Positions of the Vertex. James D. Voorhees.
16 Scurvy in Infants. William F. Cheney.

12. **Cerebrospinal Meningitis.**—Chapin points out some of the features of cerebrospinal meningitis in the present epidemic form in New York; the abrupt onset, the severity of the initial symptoms standing in some relation to the type of the attack, the contraction and rigidity, but after its characteristic beginning he finds it very irregular in its manifestations. Cases that apparently are inevitably fatal may take a turn for the better and vice versa. Tonic spasm or muscle cramp of the back of the neck is one of the most constant features. The temperature and pulse show the greatest variations without any characteristic features apart from this, some cases running their course with but little increase; others showing a very high temperature. In many cases the brain is seriously crippled and the patient never regains the former mental and physical strength. In all the cases except two the *Diplococcus intracellularis* was found.

13. **Cerebrospinal Meningitis.**—Koplik analyzes 77 cases occurring at the Mt. Sinai Hospital; 60 per cent. were under two years of age, the oldest being fourteen years. All the cultures corresponded to those described by Weichselbaum. The clinical picture, onset and general course of the disease were rather typical, though there were some variations. Neck rigidity is present, he thinks, at some time in all the cases.

Opisthotonos was present in about 70 per cent. The Babinski reflex was not so common as in tubercular meningitis where it is a constant characteristic. This sign, however, is of very little value in children below two years of age, and the Kernig symptom was also found of little value in infants. In all cases above two years of age it was present. In tubercular meningitis its presence was not so constant, but he does not lay much stress on its presence as a pathognomonic sign. Hyperesthesia and mental irritability were present in all cases. He thinks that MacEwan's sign—a hollow note over the anterior horn of the lateral ventricle—is of value in making up the clinical picture of tubercular meningitis, though it is not so common in the epidemic cerebrospinal form. If the patient sits upright and the head is inclined to one side, percussion of the inferior frontal or parietal bone will give a tympanitic note. In the epidemic form this note is not obtained in the majority of cases. The range of temperature was often very marked, wildly irregular at times. Fundal changes were not present in his examinations, though they were common in the tuberculous form. There was a leucocytosis in fully 40 per cent. of the cases, even the younger ones, but a prognosis as to recovery or fatal issue can not be made from the leucocyte count alone without taking into account other conditions. The examination of the cerebrospinal fluid showed the predominance of polynuclear cells in chronic cases, but he does not think this is of great value in determining the form of meningitis; the older the child the better the chance of recovery. He has records of cured cases in infants of five months. The most common complication appeared to be otitis. In most of the recovered cases there was little serious injury to the nervous system. He thinks the disease is a self-limited one, and that all we can do is to relieve the suffering and treat the complications. Lumbar puncture has not proven curative in his cases, though his experience has been quite extensive and there have been no accidents that might be directly or indirectly attributed to the procedure.

23 X-ray Diagnosis of an Interesting Case. L. D. Weiss.

18. **The Radiograph in Disease of the Long Bones.**—Eising points out the value of the radiograph in the diagnosis of diseases of the long bones, limiting himself to a study of inflammatory and neoplastic conditions. When the periosteum is irritated or inflamed a good radiograph will present various phases of alterations, and, he thinks, permit of deductions that throw light not only on the kind of irritation, but also on the period of time that it has been active. Hemorrhage into the periosteum or between it and the bone will be recognizable or not, according to the age of the lesion. A subperiosteal collection of pus may present the identical picture, but this point the clinical symptoms must determine. The main point, however, is to bring out the difference between osteoperiosteal neoplasms and osteomyelitis and to show the radiographic characters of the two large groups of carcinoma and sarcoma. Radiographs of carcinoma show an area of rarefaction which is circumscribed, rather sharply demarcated, not giving the mottled appearance shown in osteomyelitis. The size of the area of rarefaction is commensurate with the length of time of the clinical symptoms. Of sarcoma there appear to be two groups: 1, the myeloid or giant-celled sarcoma, very characteristic and showing an area of erosion of bone and periosteum, not of rarefaction as in the case of carcinoma, but of bone resorption, as if the part had been taken out with a gouge; 2, spindle- and round-celled osteosarcomata present different pictures. These tumors usually cause a gradual fusiform dilatation of the shaft of the bone. The bone itself is homogeneous or at least does not show the sudden transition of light and shade to be seen in radiographs of osteomyelitis. The features characteristic of osteomyelitis in the radiograph are a bone swelling occupying a segment of the bone, or perhaps the entire length, irregularly fusiform. The area of disease presents a mottled appearance, the result of irregular translucency caused by liquefied areas and small areas of density where bone has become thickened. He does not wish to imply that the radiograph is absolutely infallible, but it may, when properly interpreted, throw light on the conditions.

19. **Epidemic Cerebrospinal Meningitis.**—The use of lysol intraspinal injections in 5 cases is reported by Nammack, 4 of these cases proving fatal, 3 from complicating conditions, all in adults. In one case, an Italian boy seemed to be benefited and recovered. He remarks that the use of lysol is reasonably safe in fairly strong solutions.

21. **Rubber Tissue in the Treatment of Granulating Surfaces.**—The method advocated by Schley is to use rubber tissue, overlapping the area to be treated by several inches, after local applications of well-powdered boracic acid, and covering it with absorbent gauze, again overlapping its edges, and fixing the whole with a snug supporting bandage. As a rule the dressing should be left undisturbed for at least five days or a week, and sometimes even longer. The boric acid acts as an antiseptic astringent; the irregular surface of the gauze wrinkles the rubber tissue, giving a chance for the epithelium to climb; the smooth surface of the tissue insures a smooth surface to the granulations. He finds that this seems to work well on flat, firm, granulating surfaces, burns, etc. The possibility of toxic absorption of boric acid is mentioned, but so far there has been no such effect. The general results of the treatment in the cases in which it was applied seemed to be entirely favorable.

22. **Bilharzia Disease.**—Drs. Rafferty give additional facts in a case previously reported by Dr. Edwin Walker of Evansville in The Journal of the American Medical Association, giving here the blood and microscopic findings. The peculiarities are the occurrence of the case in this country when there has been no residence abroad, the almost universal distribution of the organism in the body, it having been accurately demonstrated in blood from the left lung, stomach, lower bowel, probably from the pelvis of the left kidney, from the peripheral circulation, in the urine, and fluid from a cyst in communication with the urinary bladder. Other peculiar features are the excessive hemorrhages over a long period of time and the resistance of the patient, who has undergone two successful abdominal operations and has been a semi-invalid for ten years.

26. **Kidney Decapsulation.**—Elliott analyzes the statistics of kidney decapsulation and points out the following facts to be accentuated as vitally affecting the subject:

1. Chronic Bright's disease in its development constitutes a diseased condition of the entire system.

2. It is a disease of very gradual development, and in the great majority of cases, has existed for months and years before the patient comes under observation.

3. It is produced by a chronic toxemia, either systemic or infective in origin, which produces coincidently as a result, widespread arterial and cardiac degenerative changes, which, being once established, are permanent, and which in their development eventually constitute the most threatening element of the disease.

4. General edema or anasarca in chronic renal disease is in many instances in great measure a cardiac dropsy, brought about by advancing myocardial degeneration. It is occasionally so in chronic parenchymatous nephritis, and almost invariably so in chronic interstitial nephritis.

5. It may be stated that, in like manner, developing anuria and uremia in chronic nephritis may be largely cardiac in production, the functional inadequacy of the kidneys having its inception in the fall of blood pressure incident to circulatory failure.

6. In the later stages of chronic nephritis, of whatever character, the case is apt to take on these cardiac aspects, which virtually convert the therapeutic problem into a question of sustaining a failing heart.

7. Albuminuric retinitis must be looked on as one of the terminal symptoms of chronic nephritis. The concordance of opinion places a limit of two years on the prognosis after development of this complication. The statistics gathered by Suker of cases operated on show that, in place of prolonging this limit of expectancy, operation has a decidedly contrary effect.

8. It is to be borne in mind that chronic nephritis is a disease of slow and spasmodic development. It is well to realize its exacerbations and remissions, so as to avoid the error of mistaking remissions for cures.

9. The mere fact that the general condition of the patient improves somewhat after decapsulation does not establish the validity of the operation, for hygiene and rest will do the same for the patient to a remarkable degree in many cases. As the factors of hygiene and rest are invariably associated with the surgical procedure, it is possible that the resulting benefit may, to some extent, accrue from those sources.

10. The results of experimentation demonstrate that, within a period of three months and a half after decapsulation, a new and, in most cases, a tougher fibrous envelope has taken the place of the original capsule. This fact may account for the many relapses and deaths after that period in cases operated on, and in chronic cases, at least, it narrows the prospect of improvement to a period of months.

27. **Kidney Decapsulation.**—Suker takes up the subject from an ophthalmologist's point of view, and concludes that at least 25 per cent. of cases of all kinds and varieties of chronic Bright's disease show evidence of retinal or other serious fundus complications. These are usually of a degenerative type, attended with like kidney change, and the cardiovascular system is, or shortly will be, seriously involved, and changes may develop without any subjective symptoms. All these may be accepted as proof of a general circulating systemic toxin, designating the acme of the development of the Bright's disease. The death rate of this class of cases under the best medical treatment is about 75 per cent. for the first year and 85 for the second, while in cases operated on it is 100 per cent. for the first year. As these fundus findings are of paramount prognostic import in an inverse ratio to the age of the patient, and as the medical aspect of the question as presented by Dr. Elliott offers as good if not far better results than decapsulation in like cases, the surgeon must consider all this in an endeavor to establish the validity of the operation. Suker thinks he has ample reasons to believe conservatively, from the facts above detailed, that he has conclusively proven that decapsulation of the kidney for chronic Bright's disease is absolutely contraindicated in such cases as present retinitis or neuroretinitis with or without hemorrhages.

28. **Puerperal Sepsis.**—The operation recommended by Chandler and which he says he has been performing for the past six years, is described as follows:

> Make an incision posteriorly to the cervix in the posterior vaginal wall; then pass a pair of long blunt-pointed forceps, slightly curved, in the cervical canal, up into the cavity of the uterus; then puncture the posterior wall of the uterus in the center, near the top of the uterus. Then introduce with two fingers a piece or strip of iodoform gauze through the posterior vaginal opening previously made, clasp the gauze with the forceps, and drag the same through the uterine wall and out through the vagina. Repeat this by puncturing the uterus on each side, but posteriorly and just about the middle of the body of the same, drawing the gauze through the same as in the first attempt.

He admits that it produces a certain injury to the organ, but claims that it is conservative, easily performed by the experienced and treats the organ as an infected part, gives drainage to the uterus and to those tissues and vessels shown by postmortem examinations as liable to be affected. The mortality is also lowered, though a larger number of cases will be required to demonstrate this than are at present available. He reports four cases.

33. **The Lymphatic Constitution and Surgery.**—Gwyer calls attention to infection through the lymphatics after surgical operation, claiming that the use of a sharp knife may sometimes assist in this infection by leaving the channels open. His own method is to occlude all bleeding vessels and, after extirpation of the lymphatics, carefully ligate the point of exit of the vessel as he would the arteries or veins. As for the lymphatic spaces, he rubs sterilized vaselin or a thick ointment, such as iodoform ointment made with vaselin or lanolin, thoroughly over all the raw surfaces. This, he thinks, occludes the lymphatic spaces and smaller vessels until there is no more danger of absorption. In case of ordinary abscess, as soon as the pus is evacuated and the cavity is washed out, he swabs it dry and throws in enough ointment to fill it. In the after-treatment of infected cases with cavities, it is his custom to fill them with ointment with each dressing or ocasionally. The ointment should be something that will dissolve, hence, he would not recommend bismuth or oxid of zinc and there should not be enough poisonous material, such as iodoform, to affect the patient.

36. **Salivary Calculus.**—Roberg reports a case and discusses the etiology. He thinks that something in addition to bacteria is necessary to explain the production of salivary calculus, and that this something appears to be a foreign body. Foreign bodies can easily enter Wharton's duct, which is the one most usually affected, owing to its size and the location of the orifice. Whether a constitutional condition can produce it is not certain. In only one case have calculi been found in more than one gland or duct. It appears probable that an increase in the total solids of the saliva may be a predisposing factor. The diagnosis is easy. The treatment consists in evacuation of the abscess, removal of the calculus and in some cases extirpation of the gland. He gives a bibliography.

38. **Gastric and Duodenal Ulcer.**—Moynihan reports an experience of 100 cases, calling attention to the fact that the operation of gastroenterostomy is so safe and its results so good that he thinks it is the most desirable operation in all cases of chronic gastric ulcer. Its success depends largely on the care and preparation of the patient, the speed in operating, the choice of a method which is simple and does not need a long exposure of the viscera, and the details of the after-treatment. Of his 100 cases there were at least a dozen that he would not have been surprised to lose, but the mortality percentage was only 2.

39. **Postoperative Pneumonia.**—The causes of postoperative pneumonia, especially the effect of ether, are treated of by Chapman, who, from his experimental studies, considers the following conclusions justified:

> 1. Prophylaxis. Care in ether-giving lessens shock and respiratory irritation, which reach their maximum when an unnecessarily large amount of ether is given. 2. The disinfection of the mouth and oropharynx by peroxid before operation is a rational precaution. 3. Adequate air space is of even greater importance in surgical wards than in medical. 4. A careful auscultation and

percussion of the chest should precede every operation, and if there be signs of disease, operations of election should be postponed until the chest condition is more favorable 5. A complete clinical record of all cases of postoperative pneumonia, together with a record of the previous state of the patient, is most desirable, and such records will in time greatly enrich our incomplete knowledge of the factors which predispose to the complication 6 It is possible to demonstrate experimentally the lesions produced by suffocation and etherization, and the sate philosophy which explains post operative pneumonitis may be applied to that which occasionally follows poisoning by carbon monoxid and illuminating gas

41—See abstract in THE JOURNAL of January 16, p 193.

46 **Injuries to the Axillary Vessels in Operations for Cancer.**—Smith has reviewed the literature of this accident, and finds that injuries to the axillary veins during cancer operations under aseptic methods are not serious. Passive edema of the arm rarely occurs, and is slight and transient. Slight hemorrhages may be repaired by lateral ligation or a running suture A forceps left in place forty eight hours may be used where the application of suture is difficult With extensive injury to the veins or when the situation of the diseased tissue makes it desirable, it may be boldly tied above and below and the lumen occluded without fear of bad results As to injuries to the artery, the material is too small to permit definite conclusions There was no permanent bad result in the five cases reported. Artifical heat during recovery of circulation seemed necessary in the cases where the artery was occluded

51 **Action of Smokeless Powder on the Skin.**—From experiments made on cadavers with modern repeating firearms using smokeless powder, Johnson concludes that the traces left are much less distinct and definite than those from black powder With the weapons used such marks cease to be produced when the distance exceeds one foot and the shot is fired at the naked skin At a distance of three inches or less powder marks may be present, but they will always be faint and may in many instances be wiped away from the skin with a wet or dry cloth If the injury is to a part of the body covered with clothing no powder marks at all will be found on the skin The clothing will never be scorched no matter how near the weapon is held If the clothing is wool no mark can be detected on it even at the closest range In linen clothing a faint mark may be found if the weapon is held at a distance of three or four inches, or less It might be possible in some instances to state definitely what sort of ammunition was used in producing the wound This might be of importance from a medicolegal standpoint He thinks further experiments in this line are desirable

53 **Topical Applications to the Upper Air Passages.**—Hinkel offers the following tentative summary in a non dogmatic way of the value of topical applications to the upper air tract Powder insufflations are an inefficient form of medication in this region Inhalations of medicated steam are useful in the early stages of catarrh and catarrhal inflammations, the higher the temperature and the greater the saturation, the more efficient is the inhalation Dry inhalation is of little use Inhalation of smoke from a smudge of suitable medicaments will usually control a paroxysm of asthma, but finely nebulized oils suitably medicated are more elegant when equally efficient Gargles are of little value unless the patient be directed and trained to use them in a way to give the greatest possible access to the pharynx and nasopharynx They can be used occasionally as an efficient means to cleanse the nasopharynx and nasal chambers Douches are chiefly used for applying cleansing alkaline solutions to the nasal passages and nasopharynx Cleansing solutions are the most important topical applications in the upper air tract and remove decomposing secretions Care must be taken that the amount is not too large or too much force used so as to carry infection to the middle ear Drugs used other than for cleansing purposes act as irritants to the mucosa or by absorption into its tissues Irritants or absorbents in the hand of the physician are best applied as pigments or sprays, directly to the region it is desired to affect, even within the larynx or trachea In the trachea the medicaments may be injected through the glottis directly on the walls. Sprays should be reserved usually for the use of the patient during the intervals between local treatment by the physician, and if the continuous influence of the drug is desired. We have good evidence of the prompt absorption by the mucous lining of the air tract of certain active drugs such as cocain, adrenalin, stramonium and atropin Further experiments as to the absorbability of the different drugs are needed for rational local therapeutics of the nose and throat It is not improbable that the massage attending the application of pigments to the mucous surface is an important factor in producing reactions in the circulation and in the glandular secretions While we still have but an imperfect knowledge of the local effects of topical applications, local therapeutics must remain inferior to surgery in accuracy of application and efficiency in the treatment of chronic diseases of the nose, ear and throat.

54 **Modern Hypnotics.**—Coblentz reviews the usual hypnotics, including those that are already well known and such new ones as isopral, veronal, etc. As regards the sulphone group, including trional, sulphonal, etc, he says it is remarkable that the by effects are so rare considering their extensive use and the frequent faulty method of application He thinks these drugs have been employed, however, in too large doses, and he finds that 15 grains of trional are usually sufficient. They should be employed in alternation with other hypnotics and with strict observance of all the necessary precautions Comparatively few really valuable hypnotics are known Insomnia is of such a varied nature that the drugs that succeed in one case may fail in another For this reason, therefore, it is well to have as many drugs as possible to make a selection In the chronic forms of sleeplessness this is especially necessary where alternations of the drugs are advisable. A combination of two hypnotics is often more satisfactory than either alone, one supplementing the other

56 **Tuberculosis**—Newcomet reports the treatment of tuberculosis with the *x* ray The results have been negative in the pulmonary cases, but he thinks it of advantage in laryngeal tuberculosis He reports cases where treatment by the *x* ray was applied for sinuses after the removal of tuberculous glands in the neck, and in some cases with marked improvement In others the results were negative He thinks in suitable cases the use of the *x*-ray will prove a valuable adjunct in the treatment of these glands without operation.

1. **Cough.**—Smith reviews the subject of cough, pointing out its mechanism, the irritants which produce it, direct and reflex, its association with special febrile diseases as well as with tracheal, laryngeal and pulmonary conditions, discussing the diagnosis of the causes, methods of examination, importance of sputum examination and treatment. He condemns gargles for the ordinary patient, and thinks that in the use of the spray apparatus an india-rubber reservoir between the pump bulb and the bottle is very necessary to keep up constant pressure. The only right way to use the spray apparatus is for the patient to hold the mouth wide open, placing the spray nozzle just within the lips, and then take several deep inspirations while the spray is still actively issuing forth. This requires a continuous current. An exceedingly useful mixture for such a spray is one composed of tincture of benzoin, compound wine of ipecac (B. P.), and a 5 per cent. solution of cocain in equal parts. This properly used relieves the cough, breaks up irritable conditions in the larynx, and is very useful when nothing is to be seen and yet the patient complains of a tickling in the throat. The avoidance of changes of temperature is mentioned as valuable. In a useful cough which clears out the lungs, precautions need not be adopted. In definite phthisis with a useful cough he has found nothing so efficacious as 8 grains of iodid of potash; half a dram of syrup of tolu, and water up to half an ounce, used three times a day. In chronic subacute bronchitis he advises the avoidance of smoking or excessive talking, and thinks the cold morning bath better than any drug for those who are accustomed to it. In other cases when the chronic cough is troublesome he finds the iodid prescription useful, but more for adults than children. In the latter, belladonna does better work.

3. **Tuberculosis in the South of Ireland.**—Wynne points out the excess of tuberculosis in the South of Ireland as compared with other parts of Great Britain, and describes the insanitary conditions that exist which account for it, the unventilated dwellings, dirty habits, etc. The remedy lies in proper sanitation, including a more efficient control of the premises and cows of milk purveyors.

12. **Disorders of the Spleen.**—In this first lecture Taylor reviews the frequency of various lesions of the spleen, including capsulitis, perisplenitis and others due to various causes, chief among which are infectious and heart diseases. He mentions enlargement which seems to be frequent after typhoid, also in connection with leukemia, liver cirrhosis, etc., especially dwelling on infection as a cause of splenic enlargement. While some of the largest spleens are produced under conditions not proven to be infectious, such as leukemia, cirrhosis, etc., the most frequent causes are enteric fever, malaria, and endocarditis, with pneumonia and tuberculosis also following at a distance. New growths in the organ are comparatively rare. The following are recognized infectious diseases in which the spleen is known to be occasionally or constantly affected: Typhoid fever, relapsing fever, malaria with great constancy, measles and scarlet fever, variola, glandular fevers in more than half the cases, Malta fever always, diphtheria frequently, influenza, Weil's disease sometimes and pyemia. In anthrax it is generally larger than natural, and in acute dysentery it is full and soft. In chronic dysentery it is usually large, but sometimes small. In beri-beri it is increased in bulk and weight, but the influence of the failing circulation may operate here in part. In tubercle the organ often contains miliary or caseous nodules, but it is certainly enlarged sometimes. Congenital syphilis is probably responsible for many enlargements in infants. He has found little that is definite as to the implication of the spleen in rubella, varicella, mumps, whooping cough, cerebrospinal fever, sleeping sickness, early acquired syphilis, tetanus, rabies, glanders, foot and mouth disease, rheumatic fever, etc. Scheube states that it is occasionally enlarged in yellow fever. It appears to be little, if at all, enlarged in different kinds of poisoning. Landry's paralysis may be added to the list of infectious diseases and also pernicious anemia. Some of these causes are reviewed in detail and the article concludes with a report of a series of cases.

13. **Gangrenous Processes of the Alimentary tract.**—The third lecture of Corner treats of the bacteriology of acute infectious necrosis in which he finds pyogenic cocci more common in the acute than chronic forms. The colon bacillus is by far the most abundant organism, occurring in 90 per cent. of the chronic cases and 70 per cent. of the acute, and associated with staphylococci in 15 per cent. of the acute cases, and with streptococci in 7 per cent. Staphylococci alone are rare; 1 per cent. in the chronic form and 4 per cent. in the acute. Streptococcus is exceedingly rare in the adult. He remarks that the colon bacillus is so common and so numerous that it must overcome other organisms and that, therefore, the earlier the case is examined the more likely are we to find complicating germs. It is doubtful if the cultures in all cases represent all the organisms that have been concerned in the dis-

aster. The colon bacillus has some bad relations, but it is not always the rule that its action is an evil one. There is every reason not to expect other organisms in an ordinary culture, as they have been generally killed off by its growth. He finishes his paper with a notice of certain of the acute infective necroses in animals, pointing out that veterinary surgery seems to be in the stage that human surgery was twenty years ago. The idiopathic peritonitis of the latter has turned out to be mainly due to the appendix, and it remains for the future, he says, to see if those of the animal will find a similar explanation.

14. **Stomach Surgery.**—Steven is not a surgeon himself, but on a basis of 23 operations performed on his patients, affirms that with careful selection there are many stomach affections which can be benefited and successfully treated by surgery. But as regards malignant disease, he fears that the results of surgical interference will be mainly palliative. In cases of ruptured ulcer, of excessive hematemesis and of dilatation the operation may be confidently expected to be beneficial if done in time. Pylorectomy in malignant disease has, in his experience, always been fatal.

23. **New Mode of Sterilizing Catgut.**—Steam has a disintegrating action on catgut and its effect is avoided by boiling the catgut in alcohol. The alcohol, however, takes up water and thus some steam is generated. Triollet believes that this difficulty can be avoided by using acetone in the place of the alcohol. The catgut needs the water after sterilization to restore its flexibility. This can be supplied without opening the air-tight jar. The catgut is wound on a small vial, which is then filled with water and placed, unstoppered, in a jar containing 10 c.c. of acetone. An air-tight metal cover is then screwed on the jar and the whole is heated for forty minutes at 120 C. The fumes of the boiling acetone hold the water down in the small vial, the pressure of the former being four atmospheres and a half and of the latter merely two atmospheres. The sterilization of the catgut proceeds, therefore, as if there were no water in the jar. After the jar and catgut are cooled again, the jar is turned upside down. The water runs out of the vial and diffuses through the acetone, and the work of softening commences. The catgut is ready for use in a few hours or days, according to its caliber.

26. **Hygiene of Textile Industries.**—Vermersch draws a gloomy picture of the conditions that prevail in the woolen spinning mills in France. The workmen engaged in spinning the wool have to work in a minimum temperature of 75 F., and it is generally 100 or above. The air has to be saturated with moisture in order to conduct away the electricity generated in the wool by the friction. In order to maintain the conditions favorable to the working of the wool, there is an almost total lack of ventilation. In some of the workrooms he found 9.3 per cent. of carbonic acid gas per 10,000, and 100,000 germs to the c.c. At the antituberculosis dispensary at Lille, 109 out of 519 applicants were employed in this industry.

28. **Occipital Neuralgia in Case of Sore Throat.**—Vincent has noted neuralgia following the course of the occipital nerve in 17 out of 136 cases of various forms of angina. He ascribes it to some abnormal communication between the pharyngeal nerve and the second posterior root of which the occipital nerve of Arnold is the direct prolongation. [He has since called attention to a slight, transient contraction of the pupil in cases of ordinary sore throat, stating that he has found it very pronounced and constant in more than one-fourth of all the cases in which the velum was particularly involved, especially in phlegmonous angina. He assumes that there must be some direct communication in certain individuals between Meckel's ganglion and the ophthalmic ganglion. Modifications of the pupil noted in infectious diseases, particularly in pneumonia, are due probably to some inhibiting or stimulating action on the cervical sympathetic or the meninges from the infectious virus. The discussion on this subject is reported in the *Bull. de la Soc. Méd. des. Hop. de Paris*, May 26, 1904. —Ed.]

30. **Arterial Atheroma and Arteriosclerosis.**—Josué does not accept any connection between atheroma and arteriosclerosis, but thinks that they are different entities. Small doses of adrenalin injected into the veins of rabbits induced atheroma in time, but nothing was ever observed in the experiments that suggested arteriosclerosis. He is inclined to think that the suprarenals are concerned in some way with the production of the atheroma. In 3 clinical cases of pronounced atheroma that came to necropsy he found evidences of extreme hyperfunction in the suprarenals, as he relates in detail.

32. **Combination of Intermittent Hydronephrosis and Enteritis.**—Debove cites instances similar to the case described, in which a floating kidney induced intermittent hydronephrosis and was the indirect cause of a mucomembranous intestinal affection. All the symptoms were cured by fixation of the abnormally movable kidney. This connection between the floating kidney and the mucomembranous enteritis has been fully established by the cures obtained by intervention on the kidney after failure of all known medical measures. Surgical interference is also indicated by the danger that the intermittent hydronephrosis may become continuous. Researches in his laboratory have demonstrated that when one kidney is in a condition of chronic hydronephrosis, the other kidney in time develops interstitial nephritis.

33. **Abnormal Acidity of Blood in Etiology of Tuberculosis.**—Canter asserts that he has found the standard of acidity of the blood in health to be between 450 and 550 acid units. In the tuberculous and especially in the pretuberculous stage, the acidity drops to 400. The lesser acidity seems to afford a more favorable culture medium for the tubercle bacillus. He suggests that treatment should aim to restore normal acidity to the blood, and in the pretuberculous stage should render the blood abnormally acid.

34*a*. **Visual Acuity in Relation to Working Capacity.**—This article was delivered as the principal address at the French Congress of Ophthalmology held in April at Paris. Sulzer emphasized the importance of adopting a uniform standard for determination of the visual acuity, which can be used by illiterate subjects and which will reveal simulation and aggravation. He proposes a scale based on a pure and simple visual impression, groups of black and white lines of equal width, and the Mellen figures. He also urged that the unit of sight should be the smallest measurable amount of visual acuity and multiples of this unit should represent the degree of visual acuity instead of the fractional figures now used. He proposes to adopt for this unit the visual angle of one degree and call it the Mellen unit. In regard to the working capacity he proclaimed that the permanent, partial incapacity resulting from the loss of an eye or reduction in visual acuity can not be accurately determined unless the limits of the professional visual acuity of the different industries and professions and their branches are known. Hence it is important to establish these limits without delay, examining large numbers of subjects representing each industry, trade and profession.

These examinations must be made with a standard scale and an illumination of at least ten candle meters.

34*b*. **Tardy Complications of Slight Injuries of the Eye.**—Dransart reported several cases of very serious lesions consecutive to slight contusions of the eyeball. The most insignificant traumatism may be followed by cataract, detachment of the retina, amblyopia without objective lesions, or atrophy of the optic nerve. Consequently the prognosis of contusions of the eyeball should be extremely guarded.

34*c*. **Vision in Deaf Mutes.**—Desjardins of Montreal stated that he had observed hypermetropia in 80 per cent. of 145 deaf mutes examined, with amblyopia in 53 per cent. In only one instance were the parents first cousins.

38 *Sarcome de l'arrière-cavité des épiploons avec considérations sur les tumeurs de l'arrière-cavité des épiploons. G. Gross and L. Sencert (Nancy).

35. **Subtotal Abdominal Hysterectomy.**—Jayle describes Pozzi's technic in performing this operation for fibroma. [Professor Pozzi, by the way, is the official delegate from the Paris Medical School to the Congress of French-speaking Physicians in America, to meet at Montreal, as already announced, June 28.—Ed.] Fifteen large cuts accompany the article, the last one showing how the stump of the cervix is sutured in two tiers. The lower part of the uterus is cut off in a point, which enables the lips of the wound in the stump to be more readily approximated. He uses a clamp to hold the broad ligaments, which has five long, sharp teeth along the lower blade, and a catch to lock the blades together. It is thus impossible for the ligament to slip out of the grasp of the forceps. He incises the ligament between two of these forceps.

36. **Menstrual Deviations.**—De Sinéty applies this term to the abnormal course of menstruation in a patient under observation. Puberty occurred with considerable commotion at the age of 12, with hemorrhages from the nose, vulva, anus and into the skin. Except for occasional irregular epistaxes there was no further intimation of menstruation until the age of 20. At this epoch vicarious menstruation through the rectum became regularly established. The vagina was walled off by a partition forming a cul-de-sac only 3 or 4 cm. deep.

37. **Purulent Collections in the Rear Cavity of the Omentum.**—Michel and Gross review the 43 cases published in the literature, and describe another personally observed. Puncture is dangerous, but incision and drainage usually cure. In the personal case described recovery was rapid after the laparotomy. Nothing was found to indicate the primary source of the pus pocket, but they assume that a very slow, chronic pancreatitis may have existed. Among other differential signs they mention that the stomach is always in front of the collection. The meteorism is more general in ileus than in case of pancreatitis. Exploratory puncture entailed fatal peritonitis in certain cases in which it was used.

38. **Sarcoma of Rear Cavity of Omentum.**—Tumors in this locality are very rare. Gross and Sencert were able to find only 4 cases in the literature, and all were teratomas, but they had occasion to operate for removal of a sarcoma in this region. The tumor was in a condition of cystic degeneration. This and the foregoing article form an elaborate monograph on the pathology of the rear cavity of the omenta.

43 *Procédé de circulation artificielle comme traitement prophylactique de la gangrène des membres. N. S. Isambert. Abstract.

43. **Artificial Circulation to Prevent Gangrene.**—Isambert was able to avert gangrene after ligature of the femoral artery on account of a traumatism. His prophylactic measure aimed to induce artificially a circulation through the parts by alternately expelling the blood and allowing it to rush back. He wound an elastic constricting bandage around the leg, and then removed it, repeating this procedure four or five times during the twenty-four hours. After each application the blood flowed into the limb much more copiously than before, showing that the paralytic vasodilatation caused a greater influx of blood than was possible before. He thinks that this mode of influencing the circulation has a wide scope of usefulness.

44. **Osteoplastic Resection of Symphysis for Access to Pelvis.**—The immense difficulties encountered in the extirpation of a malignant tumor of the bladder by Kraske, notwithstanding that he worked through both abdomen and vagina, impelled Manz, his assistant, to devise some easier means of access. He thinks he has accomplished this by the technic described and illustrated. A six-sided flap is cut in the symphysis pubis, two of the sides being formed by the top and bottom of the symphysis proper, and the other four sides being sawed with the Gigli saw through the pubic bones in the shape of a right angle on each side, the point of the angle touching the nearest point of the obturator foramen on each side. The side of the flap formed by the top of the symphysis proper is nearly four times as wide as the side formed by the bottom of the symphysis. The osteoplastic flap is turned back upward, and the access afforded to the parts below is surprisingly capacious, as the advantages of the space in the obturator foramina are gained. He has not tried this technic on the living subject, but is convinced that it will prove a great advance in the technic of operations on the pelvic organs, including the rectum and the female genitalia.

46. **Injections of Iodoformed Glycerin into the Lung Tissue.**—Gessner urges that pulmonary tuberculosis in its early stages should be regarded as a surgical disease and treated accordingly. The established principles of surgical treatment of a tuberculous lesion, that is, strict repose for four to six weeks and injection of 5 gm. of iodoformed glycerin at ten to fourteen days' interval, should be applied to the early stages of an acute tuberculous lesion in the lung as well as to those elsewhere. He gives the particulars of 7 cases thus treated. The results emphasize the value of this extension of surgical treatment to the lungs. He injects the fluid from the back into the apex of the superior lobe, two or three finger-breadths from the spinous process of the first or second thoracic vertebræ, the patient sitting up, the head bent forward, the spot of the

injection previously anesthetized with ethyl chlorid. The syringe is held at an angle of forty-five degrees from the horizontal, and the needle is slowly worked through the first interspace into the parenchyma of the lung. He inserts the needle in such a way as to make the injection in the cortical layer of the lung, toward the periphery, thus avoiding the larger vessels. For the lower lobe he inserts it in the sixth interspace. There has been no mishap in his experience to date. The more recent the infection the more striking the therapeutic results. The patient feels pain in the arm as the fluid is ejected, but there is no coughing. Once he found that he had made the injection into a cavity and the fluid was coughed up.

47. **Surgical Treatment of Bright's Disease.**—Rovsing epitomizes the conclusions of his experience in the statement that true Bright's disease is a contraindication to surgical intervention on the kidneys. By this he means diffuse, bilateral and non-infectious nephritis. He admits, however, that the surgeon may be forced to act even in this case by severe pains. On the other hand, unilateral or partial nephritis and perinephritis of infectious, traumatic or uratic origin may be relieved or cured by operative intervention. "How many patients," he exclaims, "have been supposed to be victims of Bright's disease on account of the finding of albumin in the urine, when in reality they belonged to the other category, and might have been saved by surgical intervention if the opportune moment had not been lost." Systematic microscopic and bacteriologic examination should be made in every case of albuminuria both of the urine from the bladder, and, if possible, of that from the ureters. Physicians should learn to catheterize the ureters. Co-operation between the physician and surgeon is needed here more than almost anywhere else, and physicians should not be frightened away from benefiting by the progress realized in this line during the last ten years by such exaggerated statements as that every case of nephritis should be treated surgically.

48. **Operating with X-ray Light.**—Perthes gives illustrations of an operating table for minor operations on the hands or arms, especially for extraction of broken needles. There are three pedals below. With the first pedal the operator can lower automatically the fluorescent screen which is horizontal, parallel to the table, and adjustable in a standard. With the second pedal he can turn on the electric current to start the vacuum tube into action, and with the third pedal he turns off the electric light illuminating the room. He can then inspect the field of operation through the interposed fluorescent screen and continue his operation with this aid, or by a touch to the pedals restore conditions as they were before, without the use of his hands. The table could easily be modified to adapt it to use for the legs or hip joint, reduction of fractures, etc.

51. ***Radical Cure of Inguinal Hernia by Closure of Peritoneum.***—Hofmann's experience has confirmed the great advantages of his "*peritoneal-verschluss*" method of obliterating the hernial sac. He aims to reconstitute the depression of the peritoneum between the *plica urachi* and the *plica hypogastrica*—the so-called internal inguinal fossa—in the place of the funnel-shaped opening leading to the hernial sac. He accomplishes this by exposing the hernial sac up to the parietal peritoneum, and at the point where the neck blends into the parietal peritoneum he applies a tobacco-pouch suture after opening and slitting the hernial sac. After it is slit, it is pulled well out with forceps, tied off and excised. The parietal peritoneum then spreads out flat with merely a small button protruding opposite the inguinal ring. When the patient coughs there is no longer any funnel-shaped protrusion. The operation is then completed as usual, the aim being merely to supply a support for the closure in the peritoneum within, as the hernia *per se* is obliterated. It is not necessary afterward to construct a canal for the spermatic cord, as this takes care of itself. He prefers a wire supporting suture and states that in 100 cases in which Witzel's wire suture technic has been followed there has been no suppuration and nothing has ever been noted to indicate that the wire must be removed. It heals smoothly in place, answers its purpose, and does not incommode in any way. No truss is required after the operation. The slight protrusion normally observed during straining and coughing is even slighter on the operated side than on the other.

53. **The Glove Question.**—Hanniesfahr uses gloves or not ("hand shoes," the Germans call them), guided by the circumstances of the various phases of the operation. He draws on lisle thread gloves, previously lying in salt solution, when he comes to the point of tying the suture threads or ligatures. By this means he is sure of asepsis, while his grasp of the suture material is much firmer. He remarks in parenthesis that Claudius' method of sterilizing catgut is actually realizing all and more than he claims for it.

54. **Operations on Esophagus.**—Kelling has been making a study of this subject for the last few years and recapitulates here some of his conclusions. Attempts at prothesis have not been very successful. In tamponing the conditions are the reverse of what usually prevails, and drainage must be by aspiration. The application of the Sauerbruch *air-chamber* may prove a progress in the technic of after-treatment as well as of intrathoracal operating. His previous communication on this subject was in the *Centralblatt*, No. 4.

56. **Intrathoracal Operating with Plus Pressure.**—Wilms describes a means of remedying the disadvantages of tracheotomy under the Brauer technic of hyperpressure. He slips a condom over the canula and as the pressure within the lungs increases, the condom inflates and closes the trachea air-tight.

60 Opening of Cancer Hospital at Moscow. Illustrated.

57. **Parasitic Origin of Cancer.**—Several colored plates show the details of the bodies which von Leyden assumes to be the living organisms responsible for the etiology of cancer. He presents a number of arguments in favor of this view, insisting especially on the fact that certain localities, such as the prisons in Luckau and Brandenburg, are absolutely immune to cancer. The negroes of Central Africa also seem to be comparatively immune. He quotes statistics from this country to show that cancer was at first unknown among negroes here, but has become frequent in late years. Also that cancer is more prevalent among our German than among our English population, and more prevalent the more crowded the population. He also comments on the fact that in animals the parts most frequently affected with cancer are those where foreign bodies are most liable to find lodgment, as in the eyes.

58. **The Fatal Complications of Cancer.**—Simmonds undertook to determine the direct cause of death in postmortem examination of 760 cancer subjects. One-third succumbed to the immediate effects of the cancer; another third to complications directly connected with it; 30 per cent. to complications remotely connected with it, and 4 per cent. to intercurrent disease having no apparent relation with the cancer.

62. **Typhemia Without Agglutination.**—The clinical and bacteriologic findings proclaimed that the case described was a typical typhoid with typhoid bacilli in the blood, but the Widal test was negative. Battignani is inclined to think that the lack of agglutination in this instance may have been due to unusual virulence of the germ. [In this connection we call attention to Weil's announcement that the agglutination test is much facilitated by previously warming the cultures to 122 or 131 F., as mentioned on page 1413.—Ed.]

63. **New Mode of Side-to-Side Anastomosis.**—Parlavecchio's communication was published originally in the *Policlinico*, No. 7, 1904. His technic consists in suturing the loops or organs together before opening, and making the opening between them by drawing a wire guitar string back and forth to cut the tissues. The rear row of sutures is taken first, then the thread is passed through from side to side of the proposed opening, the needle 8 cm. long, shaped like a fishhook. Then the front row of sutures is taken. The wire is then tied to the end of the thread and drawn through, and the tissues cut by sawing the wire back and forth, after which it is withdrawn.

64. **Fevers of Unknown Origin.**—Bozzolo discusses the fevers induced by the toxins of bacteria lurking ignored somewhere in the system. In a case described a high fever of sudden onset with chills, enlarged spleen, considerable anemia and albuminuria was not influenced by quinin nor mercury. No bacteria could be found in the blood, but the necropsy revealed an ulcerative endocarditis at the right auriculo-ventricular opening. The slight systolic souffle noted at the apex during life had been interpreted as due to the anemia and fever, there being no signs of mitral or tricuspid incompetency. The first symptoms had been noted in September and the patient succumbed in the following February. Another class of cases are those of what he calls the pre-cancer fever. It differs from the fever observed during the course of a recognized cancer as the latter is generally due to mixed infection. A number of Italian clinicians have observed cases of a slight protracted fever in old syphilitics, probably due to the localization of the process in some deep inaccessible organ. Mya has noticed that the children of syphilitic parents are particularly prone to fever on trivial causes. The irregularity of nervous or hysteric fevers is their most striking characteristic. Another group of fevers includes the cases of septicemia without localization or with tardy localization. The same germs may induce lesions in various organs or may induce a general infection without localizations, although the blood may be swarming with bacteria. Their products may cause more serious damage to organs and tissues than the presence of the bacteria themselves. This is especially true of the tetragonus, staphylococcus, streptococcus, and gonococcus, but is less liable with the proteus and still less with the colon group.

67. **Uterus Sound for Perforating Membranes.**—A small knife springs out of a sheath at the tip of the sound in the little instrument devised by Lisanti.

69. **Gaseous Gangrene.**—Jacobelli found the *Bacillus septicus acrobicus* in 2 cases of gaseous gangrene. He does not believe that this lesion is the work of any specific micro-organism. The bacilli he found do not produce gas in media containing sugar. Guinea-pigs inoculated with them died within twenty-four hours, with a developing focus of gangrene, but no formation of gas.

71. **Microchemistry of Strychnin.**—When strychnin poisoning is suspected the presence of the poison may be revealed by the technic which Ponzio describes. If the dose was .05 gm. characteristic crystals are obtained, and even with as little as .01 gm. the drug responds to the usual color tests for strychnin. The stomach is tied at both ends, and after removal from the cadaver is incised along the convex margin. The content and rinsings of the mucosa are diluted and filtered until perfectly clear. About 2 c.c. of the filtrate are evaporated to a syrup, diluted with alcohol, filtered and again evaporated. The residuum is diluted with distilled water containing a little ammonia to render the fluid strongly alkaline. The mixture is then shaken up with 2 c.c. of chloroform, and is then set aside in a separator. A few drops of the clear chloroform part of the mixture are evaporated on slides, when the strychnin crystals form, and are easily recognized. If the proportion of strychnin is too small for this, the color tests may still give a positive response. The microscope is not necessary for the color tests. His experiments were conducted on dogs, and a single drop of the final mixture never failed to show the strychnin crystals after the animal had ingested 5 cg. of strychnin, or even as little as 1 cg. Putrefaction does not interfere with the results of the test, nor the presence of food in the stomach. The stomach of one dog that had been killed with a dose of 10 cg. of strychnin was kept for two weeks exposed to the air without preservatives, merely tied at both ends. The tests can be still further simplified by shaking up with chloroform 2 c.c. of the filtered diluted stomach content after the addition of a little ammonia to render it alkaline. The resulting fluid is very turbid, but enough clear fluid can be obtained from the bottom of the separator or by centrifugalization to answer for the microchemical test.

Books Received.

Part V. Concerning the Effects of Saline Waters (Kissingen, Homburg) on Metabolism. By Prof. Carl von Noorden, Frankfort, and Dr. Carl Dapper, Bad Kissingen. Cloth. Pp. 92. Price, 75 cents. New York: E. B. Treat & Co. 1904.

The Practical Medicine Series of Year Books, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume V, Obstetrics. Edited by Joseph B. De Lee. M.D., Professor of Obstetrics, Northwestern University Medical School. April, 1904. Cloth. Pp. 220. Chicago: The Year Book Publishers.

Diseases of the Intestines and Peritoneum. By Dr. Hermann Nothnagel of Vienna. The Entire Volume Edited, with Additions, by Humphrey D. Rolleston, M.D., F.R.C.P., Physician to St. George's Hospital, London, England. Cloth. Pp. 1032. Fully Illustrated. Price, $5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

The Ophthalmic Year-Book. A Digest of the Literature of Ophthalmology with Index of Publications for the Year 1903. By Edward Jackson, A.M., M.D., Emeritus Professor of Diseases of the Eye in the Philadelphia Polyclinic. With Forty-five Illustrations. Cloth. Pp. 260. Denver, Colo.: The Herrick Book and Stationery Company. 1904.

Tuberculosis and Acute General Miliary Tuberculosis. By Dr. G. Cornet of Berlin. Edited, with Additions, by Walter B. James, M.D., Professor of the Practice of Medicine in the College of Physicians and Surgeons (Columbia University), New York. Pp. 806. Price, $5 00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

Obstetric and Gynecologic Nursing. By Edward P. Davis, A.M., M.D., Professor of Obstetrics in the Jefferson Medical College and in the Philadelphia Polyclinic. Fully Illustrated. Second Edition, Thoroughly Revised. Polished Buckram. Pp. 402. Price, $1.75 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

Electro-Diagnosis and Electro-Therapeutics. By Dr. Toby Cohn, Nerve Specialist of Berlin. Translated from the Second German Edition and Edited by Francis A. Scratchley, M.D., of New York. With Eight Plates and Thirty nine Illustrations. Cloth. Pp. 280. Price, $2.00. New York and London: Funk & Wagnalls.

Epilepsy and Its Treatment. By William P. Spratling, M.D., Superintendent of the Craig Colony for Epileptics at Sonyea, N. Y. Illustrated. Cloth. Pp. 522 Price, $4.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

Transactions of the American Pediatric Society. Fifteenth Session Held at Washington, D. C., May 12-14, 1903. Edited by Walter Lester Carr, M.D. Cloth. Pp. 234. Reprinted from the Archives of Pediatrics. 1903.

Annual Report of the Cincinnati Hospital to the Mayor of Cincinnati for the Fiscal Year Ending Dec. 31, 1903. John Fehrenbatch, Supt. Paper. Pp. 64. Cincinnati: The Commercial-Gazette Job Rooms Print. 1904.

Address.

THE ADAPTATION OF PURE SCIENCE TO MEDICINE.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON PRACTICE OF MEDICINE, AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT ATLANTIC CITY, N. J., JUNE 7-10, 1904.

ALEXANDER LAMBERT, M.D.

NEW YORK CITY.

A year ago this section enjoyed the pleasure of listening to the address of its chairman, in which were emphasized the advantages—in fact, the necessity—of clinical bedside instruction in medical education and the blending with this instruction of the scientific work done in the laboratories. But this deals with our duties to our successors in medicine, and after many years of struggling we can now feel assured that our successors, if properly educated, will have adequate grounding in laboratory work, and be able to apply the exact methods learned there to aid them in their clinical work of every-day practice. To the majority of men most active in the practice of medicine to-day, who graduated fifteen to twenty years ago, these advantages were not given, and they must turn, therefore, for their laboratory work to others who have specialized in these branches of medicine.

In our cities, at least, the time has practically passed when the expert physiologist, bacteriologist or even clinical microscopist can also be a practicing physician. Many young men in the early years of their professional careers are able to work in the various laboratories storing up knowledge, which endows them with broad conceptions of morbid processes; but the parting of the ways soon comes, and they must choose a life of clinical activity or else one of pure scientific study and investigation.

The graduates in medicine to-day may, therefore, be broadly divided, on the one hand, into laboratory workers who are each year endeavoring to build for the science of medicine a more exact and scientific basis, and, on the other hand, the clinicians, who are endeavoring to apply the scientific data to the prevention and treatment of disease.

Modern medicine has developed from; first, a pathologic foundation, with its increase in accurate knowledge of the results of disease; then a more accurate recognition by clinicians of the symptoms produced during life by the various pathic conditions; then bacteriology added to our knowledge of the etiologic factors in disease; and, finally, chemistry is still working out the nature of the various normal and abnormal processes, and to-day our most philosophical conception of the broad subject of infection and resistance, as summed up in our ideas of immunity, is one of an unceasing contest by means of chemical reactions, between the cells of the invading parasite and the cells of the resisting host. Physiology has continuously been a governing factor, furnishing the normal standard by which abnormal variations must be judged. Closely following each new scientific discovery, the clinicians have endeavored to apply the new facts to the prevention or cure of disease. In the prevention of disease the developments have been such that hygiene and preventive medicine have become a branch by themselves in the wide field of medicine. The scientific data applied by us clinicians have developed our knowledge of the morbid processes and materially increased the accuracy of our diagnosis, and, while they have developed a skepticism concerning the vigorous empiric therapeutics of our forefathers, they have developed a more accurate reasoning from cause to effect, and a more purposeful procedure to obtain the desired curative results.

At times, unfortunately, laboratory workers and clinicians, working separately at the same problem, have arrived at results which seemingly were at variance, and this has been the cause of unnecessary controversy; whereas, if they had worked together, the results obtained would doubtless have solved the problem more satisfactorily to both. It seems, therefore, not untimely, while we consider some of the advances made in scientific medicine which have added to practical therapeutics and increased the rapidity and accuracy of clinical diagnosis, we mention briefly some of the problems to be worked out through co-operation of the clinicians with the laboratory workers. And in this connection there is great need to recognize the fact that the mental attitude toward each other of these two bodies of physicians is not always one of confidence and mutual assistance, and that we entertain a plea for the more complete and intelligent co-operation between the laboratory worker and the clinician.

The most complete adaptation of pure scientific work to clinical medicine is the work of Behring and others in the antitoxic sera for diphtheria and tetanus, conceived and worked out completely in the laboratory before it was applied to medicine. This boon to humanity stands as one of the most brilliant achievements of scientific medicine. That the results in tetanus have not been as successful as those in diphtheria has been due to the difference in time at which the disease could be recognized and the antidote given, and also to the fact, but recently proven, that in tetanus the toxin is absorbed by the motor nerve endings in the periphery and travels along the axic cylinders, and apparently only reaching the spinal neurons along this route, and not by the blood current or lymph channels. It would, therefore, seem necessary in very acute cases of tetanus that the antitoxic serum must travel along the same channel as the toxin to obtain the neutralizing effect. Acting on these data, the injection of the serum into the nerve bundles has been tried in a few cases with successful results. One case is quoted in The Journal.[1] Two other cases are from personal knowledge, having been performed by Dr. John Rogers, Jr., of New York City, who recently has injected the brachial plexus with antitoxic serum in one case, and the sciatic nerve in the other, and obtained recovery. These cases of tetanus showed such intensity of infection that previous experience excluded all hopes of recovery.

At first it was thought that the bactericidal sera would be as effective in the therapeutic use as the antitoxic sera, but we now know that to obtain the substance deadly to the bacteria we must have a conjunction of the alexins or complements with the specific immune bodies, and that these sera practically contain only an increase of the specific immune bodies. In cases of infections, the alexins or complements are usually absent in the infected body. There is at present no known method of increasing the complements or alexins, hence the inefficacy of adding by injection only the specific immune bodies. The sera used in cholera, dysentery and plague possess some antitoxic as well as bactericidal properties, and in cholera and dysentery they have a further advantage because of the more favorable location of the infecting agents; hence these have proved more effective than the bactericidal sera of typhoid fever, pneumonia and streptococcus septicemia. Beside, the lack of alexins or complements in these septicemias, there is added a new difficulty for serum therapy, since the intracellular poisons contained in the bodies of the bacteria are not diffused into the tissues, and, therefore, do not cause a formation of antibodies. The preventive inoculation against typhoid fever, plague and cholera is the practical application of our ideas of immunity, and the success so far obtained seems to be, roughly speaking, that about 50 per cent. of those inoculated are protected against these diseases, and of those who acquire these diseases after being inoculated the mortality is about 50 per cent. less than in the uninoculated.

Soon after the phenomenon of agglutination of bacteria in the specific serum was established, Widal and Durham applied it to the familiar Widal's reaction in typhoid fever. This reaction has been of great value in the diagnosis of many doubtful cases of typhoid fever, but it has also led many clinicians astray in their diagnosis because its true value was not understood. While the reaction occurs at some period in 95 per cent. of the cases of undoubted typhoid fever, it varies greatly in the moment at which it occurs. It may be present during the first few days of the disease, or it may not occur until during a relapse or in convalescence. It usually appears about the end of the first week in bed. When a positive reaction is obtained, it means that the patient has, or has had, typhoid fever. But a negative reaction is of no more value in the diagnosis of typhoid fever than the inability to feel an enlarged spleen. The work of Courmont shows that this test is not only of diagnostic value, but may be used as a means of gauging the intensity of the infection and the resistance of the infected patient; that moderate degrees of infection show a more vigorous agglutination than mild or very severe infections. In moderately severe infections the agglutinating power of the serum reaches its maximum at the period of defervescence and falls with the fever or during convalescence, while in very severe infections the agglutination curves are low, very irregular and often show a premature fall. In relapses the curve is higher than in the initial attack, if the patient recovers; lower, if he dies. It is to be regretted that no universal standard of a reaction has been established, so that at present a reaction pronounced positive by one observer may be regarded negative by an equally well-qualified judge. The habit of some laboratories of sending out reports of "doubtful reactions" is misleading and is to be deprecated. It is especially in such tests as this that a more intelligent co-operation between the laboratories and the clinicians will be of great assistance to both.

The laboratory has become the final arbiter in many conditions and diseases of the blood. It is there that the differentiation of malaria, and often the final diagnosis, must be made. Only by such aids are we able to successfully differentiate the primary from the secondary anemias, and the various forms of leukemia. By applying these examinations of the blood and considering the leucocytes alone, we are often able to differentiate certain general diseases, and, weighing the blood findings with the clinical picture, we often obtain invaluable information regarding the course, and even prognosis, of a given disease. It is here, however, that the clinician must study to know the significance of data found; the laboratory can only give facts; the responsibility of their interpretation rests with the clinician.

Bacteriology has given us by improved and rapid methods the means of quickly diagnosticating diphtheria from the more benign inflammations of the throat. In regard to the sputum, and at times in regard to the urine, we all recognize the necessity of knowing whether or not the tubercle bacilli are present. By the examination of fluids from the lumbar puncture we may often decide whether we are dealing with meningitis of tuberculous origin or whether we have epidemic cerebrospinal meningitis.

Examination of the feces has increased our power of differential diagnosis and added to our knowledge of intestinal diseases. It has shown us the frequency of intestinal parasites and how widespread, even in the temperate zones, is the occurrence of hitherto unsuspected parasites.

The word indigestion formerly covered a multitude of conditions. The examination of the stomach contents has shown us that it covers many variations, or even absence, of normal digestive secretions, and whether this is due to an abnormal variation of the acid contents of the gastric juice or due to variations in the gastric ferments, or whether digestion is disturbed from loss of muscular motility of the stomach. It has taught us to differentiate between the variations of secretions occurring with a normal mucosa and those due to a diseased condition of the gastric mucous membrane. It materially aids us to diagnosticate between ulcer of the stomach and carcinoma. Wide as this field is, and accurate as the chemical tests of stomach contents may be, it fails us when we most need it in the early recognition of carcinoma. The recent work of William J. Mayo shows us that when the gastric contents show sufficient perversion from the normal to prove the presence of carcinoma, the disease has become too extensive to be eradicated. It is our duty, therefore, to realize that when a patient 35 years of age or more shows anemia, progressive loss of weight and disturbance of digestion that a month's careful treatment can not improve, we must seriously consider that the patient belongs to the domain of surgery, for surgery alone can eradicate carcinoma.

---

[1] The Journal A. M. A., vol. xlii, p. 313.

We are just beginning to recognize the practical value of a study in the variations of blood pressure. Formerly this seemed to belong to experimentation in the laboratory, but the convenient instruments of precision of Riva-Rocca, Oliver, Galante and Erlanger have placed this important study within our clinical reach. Crile has proved its value in estimating the degree of surgical shock. Already a fairly accurate range of normal pressure has been worked out for the medical practitioner. The knowledge obtained by the use of these instruments will increase our therapeutic capabilities, for they give valuable indications of the variations in the vasomotor control, and they seem to promise a distinct gain in a more intelligent treatment of cardiac and renal diseases, and will give valuable indications in the infectious diseases of when to give and when to withhold stimulants.

Among the brilliant results obtained in recent years in medicine is the demonstration that malaria and yellow fever are mosquito-borne diseases. The immediate application of this knowledge by Gorgas in Cuba, shows the possibility of restricting, if not stamping out, two of the greatest scourges of this continent. The knowledge of the full cycle of the malarial parasite has thus been furnished, but the etiologic factor in yellow fever remains still a problem to be worked out.

Beside the problems in immunity which are unceasingly being worked out in the laboratories. the etiologic factors of rabies and certain of the exanthemata seem nearest to solution. Negri has recently described protozoan bodies in certain cells of the central nervous system in rabies, which seem to be constant and diagnostic of this disease. Mallory has found and described in the skin in scarlet fever certain rosette-like bodies which he believes to be protozoa, and to have an etiologic relation to scarlet fever, though no claim is made that such a relation has been proved. Councilman and Calkins have described certain bodies in smallpox which are claimed to be protozoa, and claimed to have causal relations to the disease. It is too early to draw positive conclusions regarding the meaning of these discoveries, but there is hope that this new pathology of the protozoa may at last solve the etiology of these diseases. Other interesting protozoa are those found in the red blood cells in the mountain fever of the Bitter Root mountains by Wilson and Chowning, the infecting agent being possibly a woodtick, and also the trypanosoma of the African sleeping sickness believed to be conveyed by the tsetse fly.

Interesting as these etiologic studies are, there are other problems more urgently demanding a solution by us, more urgent because more commonly met with by all clinicians; these are the problems of the accurate interpretation of the condition of the kidneys as judged from our urinary analyses and the causation of uremia and eclampsia. It is not claimed that these problems are the chief problems of medicine to be solved, but they are among the most common that we daily meet with, and it would seem proper that more combined effort of clinicians and laboratory workers, acting in the closest and heartiest co-operation, should be put forth in the near future to obtain more knowledge than we possess at present.

Dr. Richard Cabot, in the last Cartwright lectures at the College of Physicians and Surgeons in New York, very forcibly drew attention to the inaccuracy of the urinary findings when compared with the pathologic conditions found on postmortem examination. We can judge from the urine that acute and chronic inflammation of the kidneys are present, or we may realize that an acute inflammation is engrafted on a chronic. Experience has taught us that the signs of renal disturbances seen in the early periods of infectious diseases are usually due to an acute degeneration, which is usually recovered from, and that these same signs coming in the later periods of these diseases are of more serious import and usually due to the serious lesions of the kidneys; but the urinary findings may not show it. In the chronic forms of nephritis, examinations of the urine often baffle us in our endeavor to gauge the condition of the kidneys, and often give but little assistance in estimating the progress of the disease, or the all-important question for the patient—that of prognosis. Albumin and casts, which are usually relied on, are often of less value than the total solids excreted; but take whatever constituents we will, our knowledge is inaccurate, and the examination of the urine, when we wish to rely on it, is often misleading.

Relying on what knowledge we have, we not infrequently find uremia developing when we least expect it, and we are as yet ignorant of its causation. All theories so far advanced, whether it be the retention of the urea, carbonate of ammonia, or of other poisons in the blood, or Traube's theory of thinning of the blood serum and increased arterial tension, do not explain it. We are often struck by the fact that uremia occurs while the kidneys are secreting a fair amount of apparently sufficiently good urine, and, on the other hand, anuria may last for days and no uremic symptoms develop, and yet the patient die apparently from cessation of kidney function. Bradford has shown how small an amount of kidney tissue is necessary to carry on the renal functions without serious disturbance in the organism. This observer removed two-thirds of all kidney tissue from dogs without apparent injurious effect. There was an increase in the amount of water eliminated, but the excretion of urea varied little from the normal. When, however, three-fourths of all kidney tissue was removed, with the increased elimination of water there was an enormous increase in the excretion of urea, and the dogs rapidly emaciated, with marked atrophy of the muscular tissue, and died from asthenia, but no convulsions or uremia developed. The theory of Brown-Séquard expressed years ago is interesting in this connection—that there is an internal as well as an external secretion of the kidney, and uremia is due more to a cessation of the internal secretion than to the retention of the excrementitious products in the system.

But our theories do not explain the facts, and only the most systematic clinical work in co-operation with quantitative urinary analysis and controlled by pathologic observation, will solve the problem, and the facts urgently demand such work.

To the physician there is no condition more trying to deal with than eclampsia; while it has usually been classed as uremia, occurring during pregnancy, its pathology, and some recent work on this condition seem to prove that there are probably several conditions classed under this name, and the kidneys are often but secondarily involved. We find normal kidneys and kidneys in various stages of acute and chronic nephritis. More striking are the lesions found in the liver, and these lesions are those of degeneration and necrosis, with multiple hemorrhages similar to those of acute yellow atrophy. The problem, therefore, is for us to solve whether we are dealing with primary renal disease, or one of hepatic or other toxemia. A recent article by W. S. Stone places these conditions very fairly before us. Nicholson has also recently drawn attention to the importance of the secretion of the thyroid gland in pregnancy and to the fact that certain cases of eclampsia with the firm, hard subcutaneous edema are cured by thyroid extract, and may be due to the lack of this glandular secretion. This is, however, but another toxemia requiring to be differentiated. In the hyperemesis of pregnancy and in the more pronounced conditions of eclampsia, abnormal substances appear in the urine which it is of the utmost importance to recognize. Leucin and tyrosin are present, and the nitrogen is excreted as carbonate of ammonia as well as urea. Excess of ammonia and not the loss of urea may be the danger signal. And every physician should recognize the fact that our ordinary urinary tests are here worse than useless; they are treacherous. Albumin gives no clew to the condition of the patient, and the hypobromite test for urea fails utterly to show in what combination the nitrogen is excreted, as it estimates both the urea and the ammonia nitrogen.

The problems here suggested are mentioned in the hope of stimulating work toward their solution. As has been said, it will require the closest co-operation between clinicians and laboratory workers. Such co-operation is, unfortunately, not always present, and one often sees the worker in the laboratory failing to appreciate the clinical situation and the difficulties of the clinician. On the other hand, clinicians are often prone to throw the responsibility of a difficult diagnosis on the worker in the laboratory, and, when he fails, to criticize the result and in turn throw discredit on all laboratory results.

Still others seem to feel that all specimens sent to the laboratory should go unaccompanied by any data, taking the position that any pathologist should immediately recognize any detached scrap of tissue from anywhere in the body. This is unfair to the pathologists, for, while science may be their forte, omniscience is not among their foibles. No specimen should be sent to a laboratory without a full clinical history accompanying it. The history alone can at times clear up the question between sarcoma and inflammatory and granulation tissue. The position from which tissue suspected of being epithelioma has been taken is sometimes essential for a diagnosis, because around the anus, rectum and genitals inflammation may cause cell nests which are not carcinomatous.

It is at least annoying to a bacteriologist to have sputum sent in absolute alcohol, or specimens in formalin, with the request for a full bacteriologic examination. It tries one's patience to have a little bloody piece of paper sent for a complete examination of leucocytes, malaria and a Widal reaction, or a heaped-up drop of blood, asking whether the cow from which it came had tuberculosis. I am drawing from experience, not imagination.

But confidence in new things is always a growth and a development, and is not spontaneous. Co-operation begets confidence, and experience aids in teaching what to do and what to leave undone. The rapidity of our future advance in clinical medicine will depend on the degree of co-operation we exert with the workers in the laboratories. It is for them to supply us with new facts; it is for us clinicians to apply these facts and to assume the responsibility of interpretation.

Dr. Douglas Argyll-Robertson, it is reported, is about to retire from active duties at Edinburgh, and take up residence at St. Aubins, Jersey. Dr. Robertson's name is familiar to the profession as descriptive of the "Argyll-Robertson pupil."

SURGICAL LESIONS OF THE AXILLARY PLEXUS.*

JOHN A. WYETH, M.D., LL.D.
NEW YORK CITY.

Temporary paralysis following a surgical operation due generally to accident or inadvertence is sufficiently common to justify the report of the following case, which I hope may be of service in preventing a similar accident to others:

While I had met with loss of function in the peroneal muscles due to the prolonged compression of the external popliteal or peroneal nerve on the fibula as it passes along the outer side of that bone, and while my attention had been called to several cases of temporary paralysis of the extensor muscles of the forearm due to a compression of the musculospiral nerve against the edge of the operating table during prolonged narcosis, or as a result of a rubber tourniquet too tightly drawn, I had never met with any case of entire paralysis of the upper extremity caused by overstretching of the axillary plexus in the operation of removing the contents of the axilla.

This experience occurred to me in December, 1903, in an operation on a woman about 30 years of age, from whose left axilla I removed a number of tuberculous lymphomata which involved the breast and necessitated the same careful extirpation of the axillary contents as is done in the operation for carcinoma. The pectoralis minor and the pectoral portion of the pectoralis major muscles were sacrificed in order to insure the thorough removal of all infiltrated tissues. The dissection was not difficult, the axillary plexus was in no way directly injured, nor were any of its branches divided excepting the usual small filaments which were distributed to the pectoral muscles. In other words, the operation was done exactly as I had performed it in a great many instances, and I was much disturbed to find that there followed a complete paralysis of both sensation and motion in the entire left upper extremity. As a rule, I entrust the elevation of the arm on the side of the operation to the care of one of my regular assistants, but in this instance, being requested by a visiting physician who expressed the desire to witness the operation from a point of vantage, I asked him to take charge of the arm and to keep it elevated during the operation. I can account for the paralysis in no other way than the hyper-extension of the arm, which stretched the three branches of the axillary plexus over the head of the humerus as it was thrown down into the axilla by the extreme degree of elevation. This was, however, my own fault, and it is not noted in any spirit of criticism, nor as a disclaimer of responsibility, for it is the duty of the operator to guard against just such accidents. About six weeks after the operation sensations of numbness and slight shooting pains suggested the return of sensibility, and this was soon followed by ability to move certain of the muscles of the member involved. These favorable symptoms increased gradually, and by the aid of massage and the earnest efforts of the patient, at this date, five months after the operation, every muscle of the arm is restored to its function and sensation is normal.

I have met with four cases of neuromata of the axillary nerves (all in women) in the course of my operative experience. Each of these cases was accompanied by severe neuralgic pains, with slight interference with freedom of motion, but in no case with complete paralysis of any muscle or group of muscles of the extremity. In two of the cases the pains became so severe that the patients were drifting into morphinism and insisted on radical measures of relief. In two instances the tumor had swelled the substance of one cord of the axillary plexus to four or five times its normal size, was fusiform in shape and tapered gradually above and below into the normal size of the cord. They were removed by excision, which relieved all the symptoms of pain, and, of course, produced paralysis of the muscles to which the fibers of this particular cord were distributed. However, in both instances the patients expressed themselves as entirely satisfied with the result, both were living ten and twelve years after the operation and were in excellent general health.

---

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee.

The third case of incipient neuroma of the middle cord of the axillary plexus came under my observation in March, 1904. The usual symptoms of darting pains along the arm and forearm were present. I exposed the nerve and contented myself in this operation with incision and removal by dissection of the thickened sheath in the direction of the nerve bundles. Three months have elapsed since the operation, and, while the above symptoms have not entirely disappeared, they are much less severe, and the patient expresses herself as entirely satisfied with the result.

The fourth case was that of a woman, 24 years of age, the mother of two healthy children, respectively 5 and 3 years of age. There was no specific history in the family, although both grandmothers had died of tuberculosis. She was always in excellent health, excepting for occasional attacks of migraine. In March, 1891, a slight swelling, which had been preceded by peculiar sensations in the arm and the forearm of that side, was noticed in the left supra-clavicular space. I was not able to satisfy myself as to the cause of these symptoms without exploration, which was advised and performed in that year. Exposure of the axillary contents disclosed two fusiform neuromata, one involving the outer and one the inner cord of the brachial plexus. These neoplasms in their middle or largest portion were fully one-half of an inch in diameter and were so situated that they were compressed between the clavicle and the first rib, unless the arm and shoulder were elevated. Realizing that excision would produce almost complete paralysis of the upper extremity, I divided the clavicle, closed the wound and immobilized the shoulder and arm in such position that union took place with the collar bone arched sufficiently high to secure freedom from pressure on these neoplasms. For two or three years after this operation, although there appeared to be still further enlargement of the neuromata, the patient's condition was vastly improved. Thirteen years have now passed, and for the last decade no further enlargement is perceptible. The left arm is larger than the right, while the forearm is quite normal. The patient's general health is excellent, and the only unpleasant symptoms which persist are occasional darting pains, usually in the left arm, but occasionally in the opposite arm and leg. A unique feature of this case is involuntary spasmodic muscular contractions during sleep. These contractions are not confined to the affected member, and are especially noticeable when the spasmodic action of the muscles of the lower jaw bring the upper and lower teeth together with a snapping sound.

DISCUSSION.

Dr. John B. Murphy, Chicago—It is common to have paralyses following this operation. This is something to remember. I have known paralysis of the deltoid to follow an operation for appendicitis. Cases of paralyses of the musculospiral are more rare now than they used to be. These cases do not always get well, and some of them will degenerate from pressure in spite of all one can do. We should avoid all extreme positions which produce pressure on the nerves.

Dr. Walter M. Brickner, New York City—Pressure paralyses should be prevented not only by avoiding any extreme tension on the arm itself, but also by changing the position in which the arm is placed from time to time. I remember a case in which there was a double arm paralysis. These cases are usually more the fault of the anesthetist than of the surgeon, although the casualties have to be accounted for by the latter. Not only the stretching of the arm itself, but also the pressure of the straps on the shoulders is a frequent cause of paralysis. Placing a roll of towels between the straps and the shoulder, or using the anesthetist's own hand, is a good scheme. Another dangerous position is for the arm to hang alongside the table. The anesthetist is responsible for this condition, and his attention should be called to the danger of maintaining the arm in one position, or of allowing it to hang at the side.

Dr. E. W. Holmes, Philadelphia—If one takes a dissection of the upper extremity with the bicipital and annular ligaments in place, and abducts the arm forcibly away from the body, with the forearm held straight, one will notice that the brachial plexus comes up sharply against the coracoid plexus, which, with the head of the humerus already mentioned, makes the points of leverage. The tension may be lessened by holding the hand in supination and flexing the forearm on the arm which may in an operation be so held by an assistant. In an operation for an aneurism of the transverse part of the arch of the aorta, I was ligating the third part of the subclavian, which was rendered more difficult by the presence of a wide scalenus anticus muscle and a posterior scapular artery from the third portion, which the Germans consider the ordinary, but in my experience in this country is an anomalous origin; anyway, it adds to the difficulty in tying the third part of the subclavian, and, I suppose, we unintentionally made undue traction on the brachial plexus. A part of the loss of power may have been due to the ligation, but the greater part was due to the overstretching of the plexus; the patient lived some six or eight weeks, but never recovered the full use of his arm. We are indebted to Dr. Wyeth for calling our attention once more to this danger of paralysis from overstretching the brachial plexus below the clavicle or by too great tension on the same plexus in its position above the clavicle.

Dr. J. E. Summers, Omaha—It is common now to use an operating table which has catches to hold the shoulders, and I have seen several cases of paralysis result from their use. These tables are very highly recommended, but they should be well padded before they are used.

THE MATAS TREATMENT OF ANEURISM.*

J. F. BINNIE, A.M., C.M., M.D.
KANSAS CITY, MO.

In 1902 Dr. Rudolph Matas presented to the American Surgical Association his classical paper on the radical cure of aneurism. Matas' method of operating combines the advantages of ligation and excision, while at the same time it is easier, safer and may be more conservative. The operation is suitable both to the fusiform and sacculated forms of the disease. After applying a constrictor above the site of disease, if in a limb, or temporarily ligating the proximal and distal trunks, if the carotid is the vessel at fault, one cuts into the sac, thoroughly removes the contained clots, rubs the serosa with gauze and proceeds to insert sutures. The sutures, preferably catgut, are first applied to the openings of all vessels entering or leaving the sac, then the deeper portions of the sac are closed by two rows of continuous Lembert sutures. The elastic constrictor is now removed, and if any blood escapes one or two points of suture are inserted to control this. The next step consists in folding the excess of sac wall on itself, and in doing so inverting the edges of the skin wound.

---

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee.

The operation carried out as described has been very successful, and in some cases of sacculated aneurism the circulation may be re-established through the repaired vessel. As Matas' operation has not yet been frequently performed, I deem it the duty of those who have had even slight experience with it to publish their results. This is my excuse for the present short paper and report of a single case:

J. K., 52 years, laborer. Fairly hard drinker, as evidenced by his statement and face. Several attacks of gonorrhea. Syphilis at 37, with apparent cure under treatment. When 25 years old was confined to bed for six months with rheumatism. Has had no recurrence of this. Developed an inguinal hernia three years ago; now wears a truss. Two years ago suffered from an acute pain shooting down the calf of right leg. A tumor soon appeared in calf and has increased steadily in size. The affected calf measures 18 inches in circumference (the normal one being 12 inches).

Examination.—One finds an expansible, pulsating tumor of the calf reaching up into the popliteal space. Well-marked bruit over tumor. Posterior tibial pulse delayed. There is no tenderness and only a little pain, which is referred to the foot.

Diagnosis.—Popliteal aneurism.

Operation.—Nov. 10, 1903, Sisters' Hospital. Chloroform. Elastic constrictor applied to thigh. Incision into the tumor through the attenuated gastrocnemius showed a cavity 6 by 3 inches in diameter, largely filled with a very dense, lamellated fibrinous mass. This mass was removed. The aneurism sac was thick-walled and markedly atheromatous. Only one opening into the sac could be found and this was closed by catgut sutures. The whole sac was now obliterated by several rows of Lembert sutures and the superficial wound closed without being inverted. Dressings were applied and the patient returned to bed with his limb elevated, before the elastic constrictor was removed.

November 17. A slight elevation of temperature led me to change the dressings, when some bloody pus escaped from the wound. There was neither pain nor redness. Drainage and cleanliness led to recovery. Up to date there has been no recurrence.

The above case was evidently one of sacculated aneurism. Efficient circulation was promptly re-established, but the posterior tibial pulse can no longer be felt. The suppuration was undoubtedly due to some avoidable contamination acting on non-resistant tissues. The details of the operation were not exactly those of Matas. It seems to me that complete closure of the sac by means of sutures must give better assurance against recurrence than closure of a portion of it by two rows of sutures and obliteration of the rest by inverting the skin. The operation, in the case of popliteal aneurism at least, is one of great ease and apparently of as great safety and efficiency.

DISCUSSION.

Dr. Rudolph Matas, New Orleans—Dr. Binnie adds one more experience to this procedure. In popliteal aneurism the procedure employed was very simple, and the simplicity of the operation is a great point. The modification in dealing with the sac is important. Suppuration persisting in a case does not at all conflict with the final results, and similar cases have been reported where the suppuration had no effect. I have had one such case in my own practice. Such cases multiply and the modifications proceed wisely. The fundamental point at first was the free exposure of the sac with a minimum disturbance of the surrounding tissues. The vessels should be controlled by suture. The size of the sac will be reduced by simple sutures in tiers. The restoration of the lumen is possible in many cases, and almost every one of the cases reported have illustrated these points. I know of eight cases in which this procedure has been tried by others with a curative effect. Various modifications present themselves in practice, and it may be possible, according to the condition of the sac, to reconstruct the vessel. Some of these modifications relate to the metastatic control. Aneurism at the root of a limb requires a different technic. Compression of the lumen must be obtained. Topographical distribution also causes certain modifications, as does the condition of the sac itself. In many cases we may be able to restore the lumen, but in any case, if this is not possible, we may do it good.

Dr. John B. Murphy, Chicago—In trauma of the popliteal artery, where aneurism follows, the mortality is enormous. I changed my method of operating on these cases to my sorrow as to results, but not to my sorrow as to my belief in the method eventually proving a good one. [Dr. Murphy then gave a blackboard illustration of his method.]

Dr. H. O. Pantzer, Indianapolis, reported the case of a patient who was shot through the thigh twelve years before, in whom a popliteal aneurism developed. He gave a blackboard demonstration of the operation.

Dr. Binnie—Dr. Murphy's method has one or two points which may be criticised. He makes one portion of the wall of the aneurism overlap the other. One portion of the aneurismal sac must be separated from the surrounding structures, which makes the sac wall even more non-resistant than before. In other words, Matas' method does not interfere with the nutrition of the wall, while Dr. Murphy's does.

Symposium on Research Work in the United States.[*]

THE CARNEGIE INSTITUTION.

J. S. BILLINGS, M.D.

NEW YORK CITY.

The Carnegie Institution of Washington was established by Mr. Andrew Carnegie in 1902. Its work up to this time has been largely tentative and experimental, seeking for information and advice as to what is most needed in its line of work.

ITS ORGANIZATION AND FUNDS.

It has recently been reorganized under the provisions of a special charter granted by Congress in which its objects are declared to be "to encourage in the broadest and most liberal manner, investigation, research, and discovery, and the application of knowledge to the improvement of mankind." In general, it may be said that its objects are similar to those of the Smithsonian Institution, which are "the increase and diffusion of knowledge."

A part of its income is set aside as a reserve fund for building or other purposes and another part is reserved for expenses of administration and printing. Omitting these, it has about $300,000 per year to expend on its work. The Carnegie Institution has asked for and obtained the opinions of many leading men in science, history, archeology and other branches of human knowledge, and has also received much advice beside, on the question as to what it should do. Of course these opinions and this advice have been more or less contradictory, but I will not waste your time by giving an account of the various schemes proposed.

THE RESEARCHES NOW IN PROGRESS.

You are more likely to be interested in what the institution is actually doing or proposes to do in the near future, and this I will try to tell you.

The first two purposes of the trust, as named by Mr. Carnegie in the original trust deed, are:

1. To promote original research.
2. To discover the exceptional man in every department of

---

[*] Presented to the General Meeting, at the Atlantic City Session, Tuesday evening, June 7, 1904.

study and to enable him to make the work for which he seems specially designed his life work.

For the first of these purposes a number of scientific men are now engaged in researches; the following are examples:

In anthropology: An ethnologic investigation among the Pawnee Indians.
In archeology: An investigation into central Asian archeology.
  An investigation of monuments in Egypt and Nubia.
  A study of Oriental art as recorded on ancient seals.
In astronomy: Measurement of stellar parallax.
  Determining the elements of the moon's motion.
  A study of the sun with special reference to eruptive phenomena and sun spots. With this is correlated an investigation of terrestrial magnetism and of changes therein. This will be of great interest, and may prove to be of great importance. It will take at least twelve years' work.
In botany: Establishment of a desert botanical laboratory.
In chemistry: Investigation of atomic weights.
  Investigation of rare earths.
In physics: Research on terrestrial magnetism.
In sociology: Preparation of the history of economics in the United States, including taxation, labor questions, etc.
In engineering: Research in locomotive testing.
In geology: Research of effects of high temperatures and pressures on various rocks.
  Research on subterranean temperatures.
In history: Research in unpublished archives relating to the history of the United States.
In biology: Establishment of a laboratory for experimental research on evolution, development and heredity, and of a marine biologic laboratory.
  Investigations on mosquitoes.
In physiology: Investigations on nutrition and food.
  Investigation on speech.
  Investigation on adrenalin.

The results of this group of biologic researches may be ultimately of great interest to physicians. The Carnegie Institution has not thus far undertaken any work in the fields of pathology or practical medicine, except that it contributes $10,000 a year toward the publication of the *Index Medicus*, which many of you know something about.

THE LIMITATIONS OF THE INSTITUTION'S FIELD.

Of course the entire income of the institution could be usefully expended in medical research, but the general principles of its work, as agreed to by the trustees, would not permit of this.

The institution will not undertake work which is being done or which can be better done by other agencies, or to enter the field of applied science except in unusual cases. It leaves the field of pathology and preventive medicine to the Rockefeller Institute, and the field of practical medicine and pharmacology to the many workers already engaged therein. It will not contribute money for the preparation and publication of treatises on philosophy, logic, metaphysics or theology, or on technology. It does not dispute that all of these are good objects worthy of aid and encouragement, but the applications for grants which have been made to it amount to $2,000,000 per annum, or nearly seven times its available income, and it is, therefore, compelled to make a selection.

THE SELECTION OF WORKERS.

In making this selection there has been kept in view the second of the two objects of trust above referred to, viz., to find the exceptional man and give him a chance. This is not an easy thing to do. Those who have shown that they are exceptional men are busy, they all have places, and the great universities and corporations are looking out for them and are ready to make places for them.

The Carnegie Institution has obtained the services of a few of them, astronomers, physicists, chemists, geologists, historians, biologists, and the possibility of doing this has several times determined its choice as to the particular line of research which it would attempt to aid.

There are a number of young men, and a few of middle age, in this country, who think that they are exceptional men, but who have had no chance to prove it.

To give some of these a chance to demonstrate their ability the Carnegie Institution has agreed to employ about twenty research assistants, allowing from $900 to $1,500 per year to each. No limitations as to age, sex or residence are prescribed, but the places are not intended for candidates for a university degree. Work of an advanced and special character is expected and the applicant should know what he wants to do, and have some definite idea as to how he intends to attack the problem. If appointed, he must report the results of his work at the end of the year. He may be reappointed.

Last year twenty-five such assistants were appointed from a much larger number of applicants. One wanted to work on an astronomical problem, two in botany, two in chemistry, two in geology, two in mathematics, three in physics, three in psychology, six in zoology, etc. At the end of the year it seemed probable that three or four really exceptional men had been found, and this is a very satisfactory proportion.

We do not yet know how to produce exceptional men. Possibly the laboratory for experimental evolution may give us some information on this point in course of time. At present the most important factor seems to be exceptional mothers. Perhaps it might be possible to have too many of them, but there is no danger of overproduction at present. They are needed in every department of human knowledge and work, in science and in art, in jurisprudence and in poetry, as organizers and administrators, as journalists and as captains of industry.

Nearly all the exceptional men are busy in some of these branches. The few who are not busy have other peculiarities which limit their usefulness; they are too exceptional. Meanwhile, there is a vast amount of good and useful work in research as well as in other things to be done by the rest of us, who are not exceptional, at all events, not uncomfortably so, but who have each his special opportunities for contributing something to the sum of human knowledge and to the welfare of mankind.

In conclusion, the Carnegie Institution of Washington is spending about $150,000 a year on researches which will require several years before definite results can be expected. It is spending about the same amount in investigations which it is hoped will give definite results in from one to three years. Probably no one man would approve of all of these undertakings as being the best possible things to do—the choice has been difficult—but we have done our best in the selections made, and shall be glad to receive advice and criticisms from all who are interested in the progress of science, and among these I feel safe in counting the physicians of the United States.

THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH.

L. EMMETT HOLT, M.D.
NEW YORK CITY.

How did Mr. Rockefeller come to be interested in medical research, is a question that has often been asked, and its answer may well serve as an introduction to our remarks. Several years ago a close personal friend first suggested this as an important field in philanthropy and one as yet wholly neglected in this country. The discovery of diphtheria antitoxin made a deep impression on his mind. He was much interested in this great achievement and in its beneficent results, and it was the presentation of the facts connected with this discovery, with the explanation of the steps by which it was reached, which I think finally crystallized his thought to establish an institute the purpose of which should be to further such beneficent work for humanity.

Once convinced of the need, the next question was, Could such work as this be done in this country? Mr. Rockefeller was led to believe that it was not the ability which was wanting here, but only the opportunity. It was explained to him that what had already been accomplished in advancing medicine in America had been in spite of the fact that our earnest and able men were either physicians in active practice, or, if laboratory workers, they held academic positions where their energies must be devoted to undergraduate teaching, little or no time being left for the work of research.

With these facts in mind a board of directors was formed, and the Rockefeller Institute for Medical Research was incorporated in the spring of 1901. Mr. Rockefeller pledged $200,000, which was to be drawn on by the board during the next ten years for this work. The purpose of the institute, as stated in his words, was "to promote original investigation into the causes, prevention and treatment of disease." This original pledge was intended for preliminary work, since neither the donor nor the board of directors had any very definitely formed plan of organization or lines of development.

It was decided that the sum placed at the disposal of the board could be used at first in no better way than to create a number of fellowships which should be placed in existing laboratories, and thus aid in carrying out investigations actually in progress but halting for lack of funds, or else, in starting new investigations which seemed especially promising. In this way it was thought that some immediate results might be reached. An additional purpose, it was believed, might also be accomplished, not less important than those just mentioned, and this was to discover where were the men in this country who were anxious to devote themselves to research work, and what were their qualifications.

The plan of making grants in the form of fellowships to aid investigation has been continued for the past three years. During this time 81 grants have been made to persons for work in this country, while with the assistance of the institute, four persons have been sent to Europe for work in the laboratories of Koch and Ehrlich, Germany, and one worker is now in Manila studying smallpox under the direction of Dr. Councilman of Boston.

The range of subjects for study has been already quite a wide one, relating not only to bacteriology and pathology, but also to practical medicine. As examples of the latter may be mentioned: the investigation of the milk supply of New York City; the study of the effects of feeding different kinds of milk in the tenements; the relation of the bacillus of dysentery (Shiga) to epidemics of dysentery and to the diarrheal diseases of infants.

By the end of the first year it had become clear to the directors that although much valuable work might be done by aiding special investigations by grants of money, the best work of the institute could not be accomplished in this way; that for its greatest usefulness centralization was a necessity, in a building of its own, with its own organization and corps of workers, whose whole time should be devoted to the work of research. A general plan embodying these opinions was presented by the board of directors to Mr. Rockefeller, who then added the sum of $1,000,000 to his original pledge to carry out the plan of the board thus presented. This was not designed as endowment, but was to be used for the purchase of land, erection of buildings, and the support of the work during the first ten years.

In accordance with this scheme a plot of land sufficient not only for the present needs, but the future requirements of the institute, has been purchased in New York, situated between Sixty-fifth and Sixty-seventh streets and fronting on the East River. Plans for a laboratory building 60 by 160 feet, five stories high, have been completed. It is expected that work will be begun on this building in the course of the next few weeks. The plans of the institute laboratory building have been carefully drawn after visits by four members of the board of directors to the important European institutes, for the purpose of getting the advantage of the most recent experience in matters of construction and equipment. It is expected that the new building will furnish facilities for work in bacteriology, pathology, physiologic chemistry and pharmacology. The general scope of the work will perhaps more closely resemble that of the Pasteur Institute than that of any other. Dr. Simon Flexner, late professor of pathology in the University of Pennsylvania, will be director in charge of the work in the new institute building. As a preparation for his new duties he is spending the present year in Europe. Pending the erection of the building, which will require at least a year, temporary quarters for the institute have been secured, and it is expected that the work will be begun in these by Dr. Flexner and his associates next fall.

The organization of the institute is such that none of the men connected with it will hold teaching positions, so that they will be free to devote their entire time to research.

While no plans have been made for teaching even small classes, as in many of the Eureopean institutes, it is expected that facilities will be afforded to outside physicians to carry on their own investigations under supervision.

With the establishment of the laboratory in New York it is not, however, expected that assisting outside investigations will be given up, although this may not be carried on to so great a degree as at present.

The next step contemplated in the development of the work is the erection of a small hospital contiguous to the laboratory building, in order to connect clinical and scientific work as closely as possible. With such a hospital it is hoped that scientific therapeutics, as well as pathology, may be studied. It has been from the beginning, and will be in the future, the aim of the institute to keep close to the practical side of medicine; three of its directors being identified with clinical medicine. At present the board consists of seven members, all physicians, and these have been the sole trustees of the fund. Thus far they have had, as doubtless in the future they will have, a free hand to organize and develop the work along the best lines, untrammeled by tradition, or by any non-professional board of directors. It has been the idea of the board to proceed deliberately, beginning in a small way, letting the institute develop gradually along natural lines, being ready to shape itself to new needs as they might be presented.

THE MEMORIAL INSTITUTE FOR INFECTIOUS DISEASES.

FRANK BILLINGS, M.D.

CHICAGO.

The institute of which I desire to speak to you can not rank in wealth with the other institutions mentioned. It is small, modest in its beginning, and has for its location Chicago.

The Memorial Institute for Infectious Diseases was organized January, 1902, by Mr. and Mrs. Harold F. McCormick, of Chicago, in memory of a son, who died of scarlet fever in January, 1901. At first their object was to study the cause of scarlet fever alone, but a few of their friends of the medical profession persuaded them that the conduct of a laboratory alone for the study of the cause of this disease was not the proper method of procedure, and the founders finally modified the plan by incorporating a hospital with it, and it was then named the Memorial Institute for Infectious Diseases. The institute has been wrongly named in some periodicals as the McCormick Institute for Infectious Diseases.

The founders desired to begin work at once, and within one year of the death of their son two isolated houses were rented from the Presbyterian Hospital of Chicago, in which were placed ten beds, and arrangements made with the Presbyterian Hospital for the care of these patients, nursing, feeding, etc., and the experimental work was carried on in the pathologic laboratory of Rush Medical College. Dr. Ludvig Hektoen was chosen its director, and he with a corps of assistants, has been busily engaged ever since. The board of directors consists of five, three of whom are medical men and two laymen, one a relative of the McCormick family, who are thoroughly in accord with all efforts that have been and are being made for scientific work.

Within the last year one individual gave the institute a block of ground, situated on the South side of Chicago, worth at least $150,000. Another individual has subscribed a sufficient sum of money to erect a laboratory and a pavilion to contain beds for the treatment of at least fifty people. We hope to erect this pavilion and laboratory within a year. Within the last year Mr. and Mrs. McCormick generously donated a sufficient sum of money to endow the *Journal of Infectious Diseases*, probably the first endowed medical journal in the United States. This journal will be issued monthly, or as often at least as a sufficient amount of material has accumulated for this purpose.

The scope of the work of the institute will be to investigate all of the acute infectious diseases except smallpox. The ordinances of our city prevent us from investigating and taking care of those cases in the institute. By request, the present efforts will be almost entirely directed to scarlet fever.

During the first year 125 cases of scarlet fever were treated and investigated; during the second year 85.

The enthusiasm with which the work has been received in Chicago gives promise that there will be other contributions for the erection of pavilions and the treatment of measles, whooping cough and other infectious diseases. Later on we may hope to grow until we may treat or investigate any of the infectious diseases.

RESEARCH WORK AT THE HARVARD MEDICAL SCHOOL.

HAROLD C. ERNST, M.D.
BOSTON.

The data for this summary of research work done in connection with the Harvard Medical School, were obtained from answers to the following questions: As to how many individuals are connected with the department—both as teachers and engaged in research; as to how many places for research workers—in addition to the regular teaching force—exist in each department; as to whether there are any funds that can be drawn on for the assistance of research work independently of the money contributed by the school; as to what the facilities for research are; and as to what researches are now being carried on in each department.

Questions of this nature were addressed to all the departments in the school having laboratories attached to them, or having influence over laboratories not directly under the control of the school.

In making up such a summary as this, at this time, the present condition of affairs is all that is considered. No account is taken of the new buildings of the school, now being erected, nor of the very greatly increased facilities that will be at the service of the departments, when these buildings are completed.

There appear to be fourteen such departments, or laboratories, engaged in research work, as commonly understood—excluding, in this instance, clinical research.

In summarizing the replies obtained to the questions, it is exceedingly difficult to make exact statements, but the attempt will be made to claim no more than is properly to be allowed to the influence of the school.

Taking up the departments in order, the first would be that of anatomy, and the head of that department makes the statement that there are thirteen instructors and others in the department, more or less actively engaged in research work; that there is an indefinite number of places for research workers (on the table the number is placed at ten); that there is a small fund that can be drawn on for the assistance of research work; that the facilities for anatomic study are abundant; and that there are five distinct lines of research now being carried on in the department.

The department of histology and embryology states that there are four instructors, and others, engaged in research; that there are three places for research workers; that there are no funds that can be drawn on for the assistance of research; that the facilities are those of a first-class laboratory, with a very large and unique collection of serial sections of embryos, and a first-class working library; and that there are seven researches being carried on at present.

In the department of physiology there are five instructors and others, engaged in research; there are eight places for research workers; there are funds that can be drawn on for the support of research work; the facilities are those of a well equipped laboratory, together with a large library; and that there are eight researches being carried on.

In chemistry there are nine instructors and others engaged in research; there are about fifteen places that can be occupied by research workers; there are no funds that can be drawn on; the facilities offered are fair, together with a good working library; and there are eight researches now being carried on.

In pathology there are sixteen instructors and others connected with the department and engaged in research; there are twelve places for research workers; there are no funds; the facilties are excellent, together with a good working library; and there are nine major and some minor researches now under way.

The next two laboratories are more or less intimately allied with the department of pathology, for the reason that the heads of these laboratories are a part of the teaching force of the school, but their direct control, together with the funds and the library, are under the trustees of the hospitals to which the laboratories belong.

The first is the laboratory of the Boston City Hospital, in which there are eleven instructors and others engaged in research; there are fifteen places for research workers; there are no funds that can be drawn on; the facilities are very extensive, together with a large hospital library; and there are at least ten researches now being carried on.

The second is the laboratory of the Massachusetts General Hospital, in which there are two instructors and in which there were twenty-five research workers in 1903, with about twenty places permanently open; which has a considerable fund for its support; has excellent facilities and a large hospital library; in which there are seven researches now being carried on; and from which twenty-one were published during 1903.

The next department of the school is that of bacteriology, in which there are sixteen instructors and others more or less actively engaged in research; there are ten places for research workers; there is a small fund that can be drawn on for the assistance of research work; in which the facilities are those of a well equiped laboratory, together with a good working library; and in which eight researches are now going on.

Affiliated with this department in the same way, and for the same reason that the laboratories of the Boston City Hospital and the Massachusetts General Hospital are affiliated with the department of pathology, but, of course, entirely independent of it, is the laboratory of the Board of Health of the city of Boston. The head of this laboratory is an instructor in the department of bacteriology in the medical school, and in this laboratory are engaged three instructors and others; it has about ten places for research workers; but it has no funds that can be drawn on for research work; its facilities are good, and there are now eight lines of research being pursued.

The department of comparative pathology reports that there are two instructors, with five places for research workers; that there are no funds that can be drawn on for the assistance of research work; that the facilities are fair at present, and that there are three researches now being carried on there. The head of this department makes the note in his communication that subjects are not listed as researches until they have actually reached the point where something worthy of publication has been accomplished.

The department of hygiene has two instructors; three places for research workers; has no funds that can be drawn on; has the equipment of a chemical laboratory, together with a small bacteriologic equipment; and is pursuing seven researches at present.

The division of surgery of the medical school has four instructors and others engaged in research; and has places for about ten research workers in the various hospital laboratories and in the school, together with considerable funds that can be drawn on for the assistance of research, although these funds are not under the control of the university, but under that of individual members of the division of surgery; its facilities are good; are distributed in the medical school and in the hospital laboratories; and eight researches being carried on under the direction of the division.

Affiliated with this division of surgery is a laboratory of surgical pathology, which has one instructor, with ten places for research workers; with no funds that can be drawn on for the support of research work; and which is "sufficiently well equipped"; there are six researches now being pursued.

The department of pharmacology and experimental therapeutics has three instructors, together with two places for research workers; has no funds on which it can draw; its facilities are limited, but include a fair working library; and there are about five researches now being conducted on the pharmacology of different poisonous plants.

A summary of these reports, placed in tabular form, brings out some interesting points.

In the first place it can be seen that there are fourteen departments and laboratories more or less directly under the control or influence of the school. There are ninety-one instructors and others more or less actively engaged in research; there are from 128 to 140 places that can be occupied by research workers; there are only five laboratories that have any funds whatever that can be drawn on for the support of research, and of these five, two are not under the control of the university; the facilities are, in the majority of cases, extremely good, and the number of researches actually being carried on is over one hundred.

Another interesting point is the literary side of the work; there are collections of books of sufficient extent to be dignified by the name of working libraries in nine of these departments (two of them, however, not under the control of the university), and there are five card catalogues maintained with more or less activity, giving access to the literature of the subject in which the department where they are placed is especially interested. There are over 150 different periodicals, in all languages, regularly received in the school building in these different departments, and there are four journals of scientific medicine—the editorial control of which lies in members of the teaching force of the school.

The striking point in regard to the whole summary is the very great amount of activity that is manifested in this center of medical teaching in contrast with the exceedingly small pecuniary support that it has to rely on.

THE WILLIAM PEPPER LABORATORY OF CLINICAL MEDICINE.

ALFRED STENGEL, M.D.
PHILADELPHIA.

The three great institutions that have been spoken of—the Carnegie Institution, the Rockefeller Institute and the Memorial Institute of Chicago—differ materially from that of the small affair for which I am called on to speak. To borrow a quotation, if one were to compare cubs with lions, the smaller institutions, the clinical laboratories, have a very important work to perform, and one which will in the end compare favorably with the work of the greater institutions in this particular, namely, that their work is so very much more far reaching. The clinical laboratory is intended to subserve a double purpose, not only to furnish facilities and a place for investigations, but to elevate the tone of the staffs of hospitals with which these laboratories are connected.

The founder of this laboratory, who named it in honor of his distinguished father, professor of the practice of medicine in the University of Pennsylvania some time before him, recognized that there was a change in the science of medicine, in the teaching of medicine, and that laboratories were moving away from the practical department, and particularly from that more practical laboratory, the hospital. He, with great sagacity, I think, conceived the idea of establishing a bond of union between the scientific and the essentially practical in the foundation of laboratory knowledge, so that research work could be carried on by those who were practical men to a certain extent.

The founder of this laboratory forbids undergraduate teaching within its walls, the purpose being to exclude from the laboratory or from the institution the temptation of ever running the laboratory for undergraduates. It is to be thrown open at any time to any physician who may apply for the purpose of carrying on any research work, provided he can show a capacity and previous training which will justify him in availing himself of the opportunities furnished by the laboratory. The work of the laboratory, which was established in 1895, has led to the publication of a number of research works from time to time. There have been works published at different times by from fifteen to twenty-five workers, and the laboratory is affiliated with the laboratory of the State Live Stock Board, in which Ravenel and others are carrying on investigations with reference to tuberculosis.

Clinical laboratories are of recent establishment. On the occasion of the opening of this laboratory Dr. Welch, who made one of the principal addresses, stated that the first laboratory comparable to this was established in Munich at the suggestion of von Ziemssen in 1885. The second laboratory of the kind was one which was established at Leipsic by Professor Curschman in 1892. This in point of time is the third of its kind that has been established, and I am led to believe from the amount of correspondence I have had on the subject that there are many other laboratories connected with hospitals that have been established under the inspiration of this one. The work of such a clinical laboratory can not be so far reaching as that of institutions which can liberally endow the workers as well as furnish unusual opportunities. The work must be confined more or less to the staffs appointed by the hospital with which it is connected. As a practical illustration, it is well to have such laboratories associated with hospitals, and I may refer to the fact that the Pasteur Institute, the Rockefeller Institute, and the Memorial Institute mentioned have under contemplation attachment to hospitals for practical work in association with laboratories. This is an important relation, but the greatest work which the Pepper Laboratory has achieved, if it has achieved this, is to have furnished an example for the establishment of other laboratories in connection with hospitals where research work may be conducted. The readiness with which young men who will do good work, and who will give themselves up to the best work that can be done, speaks well for the necessity of such institutions as this. The effect is to elevate the tone of the staffs of hospitals and all those who come in contact with them in any way.

Symposium on the Mutual Relations of the Government Medical Services and the Profession.[*]

WHAT CAN THE SERVICES DO FOR THE MEDICAL PROFESSION?

VICTOR C. VAUGHAN, M.D.
ANN ARBOR, MICH.

I have been asked and have reluctantly consented to briefly summarize what the medical services of the Army and of the Navy and of the Public Health and Marine-Hospital Service can do for the medical profession. I wish that this task had been assigned to someone more competent to speak on the subject than I. My knowledge of each of these services is limited and superficial, and undoubtedly I shall commit in this short talk many sins of omission. However, I am limited in time, and must speak without circumlocution.

Each of these services has rendered more or less of value to the medical profession in the past, and the best prophecy of what will be done in the future is to be found in what has been done in the past. The work of William Beaumont, as an illustration of what may be done for the advancement of scientific medicine under most adverse circumstances, is almost without a parallel in the history of our profession, and this work certainly should be credited to the medical service of the Army. Had it not been for the intelligent and sympathetic interest taken in his researches by the first surgeon general, Beaumont with all his energy and devotion to the problem which he attempted to solve, could not have prosecuted the work as successfully as he did. The surgeon general granted Beaumont frequent and prolonged leaves of absence in order to give him time and opportunity to carry on his experiments; supplied him with rare and costly books bearing on the physiology of digestion, and, in short, did everything possible to assist this early pioneer of

---

[*] Presented to the General Meeting, Wednesday evening, June 8, 1904.

American medical science in his attempt to advance human knowledge. From 1800 to 1861 many army surgeons made more or less valuable contributions to the world's knowledge of the botany, zoology and ethnology of the country west of the Alleghenies. As a type of such work I will mention that of Pitcher, whose writings are found in the large volumes edited by Schoolcraft and published by the government. The War of the Rebellion developed in both the medical service of the Army and that of the Navy men who have enriched the profession by original contributions, and the medical and surgical history of this war contains much of real and permanent scientific value. The editorial work done on these volumes by Woodward, Otis, Huntington and Smart is deserving of the highest professional recognition, and much could be said, had I time, of the many and valuable contributions contained in these great volumes, contributed by earnest medical men, many of whom made thorough records of their cases on the field, in camp, and in hospital. The library of the surgeon general has placed at the disposal of the profession in this country, under certain necessary restrictions, one of the most complete lists of medical books to be found in the world. The index catalogue and the *Index Medicus* enable us to find ready reference to the medical literature of the world. It is difficult to estimate the value that this great medical library is to our profession. It is widely appreciated and largely used by earnest medical men in every part of our country.

Barton of the Navy and Lettermann of the Army deserve credit for securing the proper organization of their respective corps. Sternberg of the Army deserves especial credit for his early and thorough work in bacteriology, and especially for his investigations in yellow fever. He showed quite conclusively that this disease was not due to bacteria, and it was necessary that this demonstration should be made before there was justification to look for the cause of this disease elsewhere. Carter of the Marine-Hospital Service, by his intelligent observation of the period of incubation in yellow fever, did much to put Reed on the right path in the brilliant investigations carried on by the Army Commission in Cuba. The work of Reed, Carroll, Lazear and Agramonte, which terminated in the discovery of the fact that yellow fever is transmitted by the stegomyia is one of the brightest pages in the history of science, and the practical application of this discovery by Gorgas of the Army and Ross of the Navy should convince all intelligent people of the beneficence of preventive medicine. Turner, Gihon, Siegfried and Wilson of the Navy were earnest and productive workers in hygiene. We are largely indebted to LaGarde of the Army and Stitt of the Navy for their careful work on the effects on the human body of modern small caliber projectiles. Coues and Shufeldt of the Army and Flint, Ruschenberger and Jones of the Navy have made valuable and original contributions to natural history. Beyer, Kitter and Wales of the Navy deserve honorable mention for their papers bearing on pharmacology, physiologic chemistry and therapeutics. The Marine-Hospital Service early appreciated the possible value of diphtheria antitoxin and sent one of its most competent men to Europe in 1894 for the purpose of studying this preparation. The work of Kinyon of the Marine-Hospital Service at San Francisco, subsequently confirmed by the able board of experts sent by the surgeon general of the Marine-Hospital Corps to San Francisco, deserves commendation from the profession. The study of the prevalence and geographical distribution of hookworm disease in the United States, so ably conducted by Stiles of the Public Health and Marine-Hospital Service, is a credit to the profession as well as to the service for which the work was done. The investigations carried on by Strong, Craig, and others of the Army on malaria and other tropical diseases, have contributed largely to our bacteriologic and clinical knowledge.

I have made these brief references to what has been done in the past in order to remind you that the medical profession is already largely indebted to the federal medical services for valuable contributions. It is true of the men in these services, as it is true of those of us in civil life, that much has been left undone; that we have not been sufficiently attentive to scientific medicine; that we have not always utilized even those opportunities that come to hand; that we have sometimes fallen into slothful and careless ways; but I have said enough to show that all of the services that I have been called on to discuss have not been without value to scientific medicine, and I will now turn to a statement of what, in my opinion, these services may do in the future for the advancement of our profession. As time presses on me, I will condense my views on this subject and state them as follows:

1. In all of these services scientific research should be encouraged. This encouragement should manifest itself in the first place by furnishing competent energetic men in the service with every facility possible to carry on any research that they may desire to undertake. There is no Army post, naval station, or marine hospital at which scientific work might not be done if the man is there to do it, and if he has the facilities to work with. In the second place, men in all these services should be brevetted for meritorious scientific work. The man in the line is encouraged to do his best because he is always conscious of the fact that for service of signal value a reward comes with a fair degree of certainty. Why should this not apply to men in the medical service? Again, men in any one of these medical services who are willing and competent to undertake research work should be detailed to study in the best laboratories in this and other countries. This in and of itself would be considered by many as a reward for meritorious service.

2. Men not in these services might be called on more frequently than they have in the past when some problem is under investigation, and when such men possess unusual knowledge along the line of study. An admirable illustration of the good that may come from the selection of a commission outside of the service is that furnished by the plague commission sent to San Francisco by the surgeon general of the Marine-Hospital Service.

3. Special commissions consisting of men in the service or of those in civil life, or mixed commissions, should be more frequently sent out to study tropical diseases. The brilliant record made by the Reed Commission in studying yellow fever in Cuba should stimulate work along this line and should lead to the sending out of other commissions. The Army Medical Service should not rest on its laurels, so brightly and so dearly won by Reed, Lazear and their fellows, but should continue to work. It should not be left to an English or a French or any other foreign commission to confirm and amplify the work done by the Reed Commission. There is much work still to be done before the etiology of yellow fever is fully understood, and why should not our country undertake this work?

4. The Public Health and Marine-Hospital Service should see to it that its new laboratory at Washington is thoroughly equipped with the best apparatus and the best men. The profession of medicine in the United States will not be content until this laboratory turns out researches comparable with those contained in the Arbeiten and Mittheilungen of the German health office. There are many problems which could properly be investigated in this laboratory with profit to the profession and the people at large. For instance, why should not this laboratory undertake experimental studies leading to advanced knowledge concerning the preparation of streptococcus and antitoxin. In order to prepare successfully such an antitoxin it will be necessary to have more exact knowledge concerning the toxin produced by the streptococcus. The study of this toxin might very properly be carried on in this laboratory. Again, we are at present at sea concerning a standard for antitetanic serum. Must we wait for Germany to establish a standard for us?

5. The Public Health and Marine-Hospital Service should establish research laboratories on the Isthmus of Panama, in Porto Rico, in the Hawaiian Islands, and in the Philippines; and should not only encourage the men in this service to make use of these laboratories, but should throw them open to competent men from civil life who might wish to study the diseases of these regions. There are many men in our laboratories who have already done excellent research work on some of the tropical diseases, and who would gladly go to one of these

countries if they could find there facilities for carrying on their research.

6. The naval medical service should equip every man-of-war with a complete clinical laboratory, including optical instruments, bacteriologic and chemical apparatus and material, *x*-ray outfit, and, in short, everything found in the clinical laboratories of our best hospitals, and the head of this department should give those in the service to understand that they are expected to use these facilities and he should reward them for work well done and censure them for neglect of duty when work is not done.

In conclusion, I may say that the medical profession of this country acknowledges with pride what has been accomplished by the federal services in the past, and it expects that in the future these services shall keep abreast of the best men in the civil practice of medicine. For the heads of these services to be satisfied with less, is not to be expected of them. When they do more they are to be commended. All of these services now have their laboratories of research more or less well equipped, and the medical profession of this country expects that these laboratories shall be the birthplaces of new knowledge.

WHAT CAN THE MEDICAL PROFESSION DO FOR THE ARMY?

W. C. BORDEN, M.D.
Major and Surgeon U. S. Army.
WASHINGTON, D. C.

In considering the subject assigned me, I am greatly impressed by the motive underlying the title. The fact that this, the largest and most representative association of medical men in this country, propounds such inquiry is pleasing evidence that it appreciates the obligations which it bears to the country, and to meet such obligations is willing to do what it can to strengthen the arm militant of the nation. It is further evidence of the trend of thought of the medical profession toward a broader and more comprehensive grasp of the duties and responsibilities which must by right devolve on it.

With the extension of medical knowledge, its quick dissemination by journal and book and the association of members of our profession together in societies, which association has been made generally possible only in recent years through the facilities for rapid travel now offered, the profession is coming to a comprehension of those broader duties which must devolve on them—duties entirely outside those connected with the ordinary routine of their profession. In large, these duties are mainly connected with the preservation of health through the making of sanitary regulations and laws and legislative enactments protecting the public against the danger incident to the practice of the profession of medicine by unqualified men. In all these matters the medical profession, comprising as it does members of the community especially educated and qualified to advise on the question of the protection of the public health, must give to the community the benefit of its special knowledge or fall short of its highest duties. Equally, though less manifest in time of peace, those arms of the nation—the Army and Navy—which require most careful preparation for effectiveness in war, require for their proper organization that the problems dealing with the health and care of armed forces should be carefully considered, thoroughly worked out, and duly solved before the time of war and stress. Provision should be made for the care of the sick and wounded, and equally and of even greater importance, adequate means for the preservation of the health of the armed force in time of war should be provided. An army is a costly institution, maintained by a nation for use in time of need; how much more costly to a nation, therefore, when in time of stress it is found inefficient. The strength of any chain is the strength of its weakest link; each link, therefore, of the organization of an army should be perfected and strengthened to correspond with the others.

In the organization of an army the Medical Department is by no means the least important link in the chain of organization. The strength of an army depends not only on proper organization and adequate training, but on the health of its individual units, and on the maintenance of the health of an army may often rest the balance of victory or defeat.

In our country the policy is to maintain a small regular army in time of peace, this to serve as a nucleus about which volunteer forces may assemble in time of war. In the same way the Medical Department of the Regular Army is to serve as the nucleus about which volunteer medical officers shall form. It is evident that for effective expansion the Medical Department must be sufficiently officered to do all regular duty pertaining to the Army in time of peace, or it will be entirely insufficient in size to properly serve as a nucleus in time of war. This was fully illustrated in our Medical Department in the war with Spain and in the British service in the Anglo-Boer war. In fact, it was so forcibly impressed on the British Commission to investigate the care of the sick and wounded in the South African campaign that this commission gave expression to the opinion which may be considered axiomatic, that a department not sufficiently large to properly perform its duties in time of peace can not be efficiently expanded in time of war.

It may be at once stated that at the present time the Medical Department of our Army is insufficient in size to meet these requirements; so much so, in fact, that in addition to the regular force of about 300 medical officers allowed by law, some 200 contract doctors are employed.

One of the pressing needs of the Army, therefore, is that the Medical Department be increased in size to such extent, at least, that it may be able to do all ordinary duties in time of peace, both for effectiveness in time of peace and to insure preparedness for war.

On the outbreak of the war many difficult problems are presented in connection with the organization of an enlarged army, largely composed of volunteer forces. The military surgeon is a specialist of type unknown in civil life. He has to deal with sanitary questions which have to do with the health of massed bodies of men placed in the peculiar environment incident to life in the field of war; also he has to provide for the shelter, feeding, medication, treatment and transport of the sick and wounded, duties which can only be properly done by men conversant with the many technical details incident to such work. To take inexperienced and untaught men and give them such duties has in the past, and will in the future, be followed by disaster. When such disaster occurs, then the need for an efficient medical service in the Army is brought home to the country, and the people cry out against a system which leads to the suffering and death of fathers, husbands, and sons sent to the country's defense, not realizing that the faults of the system may have been repeatedly pointed out and that the system has continued only through neglect to provide proper legislation. To the people at large, with peace comes forgetfulness of the lessons of war. The lessons remain only with those who, by experience or teaching, appreciate those dangers in the future which are pointed out by the experiences of the past. So far as the Medical Department of the Army is concerned, these lessons are most fully appreciated by the medical profession, and the profession can do much for the Army by applying their knowledge of these matters to the public good, to the end of remedying those evils which arise through neglect of precautions when the people forget. So in this as in other matters having to do with the maintenance of health and the prevention or amelioration of suffering, the medical profession, which is by education and experience, trained to see, must be the teachers and the leaders of the people.

But it is not in war alone that the medical department of an army is of service to a nation. In our country we have but to point to the scientific attainments and the work of Beaumont, of Otis, of Woodruff, of Billings, of Sternberg, and of Reed, as well as to the able way in which most difficult sanitary problems are now being solved and public work is being quickly and adequately done by medical officers of our Army in the far East

So in peace as well as in war the medical department of an army has its uses and reason for its existence.

The medical profession can do much for the Army by using its great influence to show that to serve the country and to protect the nation, and the individuals of the nation who go out to its defense, the Medical Department of the Army must be sufficiently and properly officered to give efficiency. More than this, as volunteers must be relied on, there should be in the country a number of reserve medical officers whose services can be available in time of need. A medical reserve has been designed to take the place of the anomalous and unsatisfactory contract surgeon system which now obtains.

Surgeons under contract have no rank, and the lack of dignity which pertains to their position has long been the subject of remark as not compatible with the standing of members of a learned profession, whose duties and responsibilities are at least equal to those of other commissioned officers. More than this, it is the experience of all armies that physicians serving with troops can not effectively perform the duties required of them unless they have the military standing given by commissioned rank. To remedy these evils it is proposed to replace the contract surgeons by special commissioned medical officers, whose commissions shall be operative only while the holders are on active duty, but whose commissions are continued so that the holders may be available for service, on their own consent, when emergency requires. Both the increase of the Medical Department and the formation of a Medical Reserve Corps have been carefully worked out, and in the form of a bill is now before Congress. This Association, both through its Committee on Legislation and by individual efforts, has been actively and effectively engaged in a campaign of education to show the need of proper legislation for insuring efficiency in the Medical Department. The medical profession can do much for the Army by furthering the efforts in this direction.

WHAT CAN THE MEDICAL PROFESSION DO FOR THE NAVY?

SURGEON CHARLES F. STOKES, U. S. NAVY.

WASHINGTON, D. C.

An opportunity to tell the medical profession of the United States, through this, its greatest organization, what it can do for the Navy, is one of supreme importance to the body of officers which I represent, and, although the time allotted to each paper is of necessity short, I trust that my efforts will be rewarded by a substantial growth of the interest which first suggested this symposium.

Recent legislation has authorized an increase of 150 in the medical corps of the Navy, to be accomplished by a yearly addition of 25. At the end of five years the corps will have almost doubled itself by a growth from its present strength of 250 to nearly 400 officers. This great increase must be accomplished by the exercise of extreme care in the selection of desirable persons from among the candidates presenting themselves for examination. As this choice is entirely in the hands of the medical corps itself, and is absolutely free from political and other influences, merit alone counts. Permission to appear before the board is extended to all citizens of the United States of good standing between the ages of 21 and 30 years. In all other branches of the service a special designation is required before a candidate may present himself for examination. If this important duty is not wisely and faithfully performed, if the corps is encumbered with indifferent material, then we alone are responsible for the unhappy conditions that will follow.

It is my belief that the medical profession can best serve the medical corps of the Navy by acquainting itself with what the Navy offers competent physicians in the way of a career, and by sending some, at least, of the best products of its schools and hospitals before the medical examining board.

I shall, no doubt, be accused of taking a grossly practical side of the topic under consideration, but I feel that the great importance of keeping up the standard of efficiency in our corps justifies the choice.

The welfare of the entire Navy is largely dependent on the efficiency of its medical officers. We have to decide—and our decisions are final—on the physical fitness of every officer and man, not only for admission, but also for promotion, and we care for each one during his whole naval career. We must study the hygienic features of his environment, and we must keep up his physical standard, so that when the supreme moment is at hand both officers and men will be found capable of responding to the call as American crews alone can respond. Superiority in personnel has oftentimes overcome superiority in ships, and it always will be so within certain limits.

A glance at the Surgeon General's report for any recent year will convince the most skeptical that the work done in our naval hospitals, the purely professional work, is superb. The field is as broad, in fact, is much the same as that encountered in hospitals of the same size elsewhere.

It has been said by our hypercritical brothers on shore that we hibernate professionally while serving on board ship. To correct that erroneous impression let me tell you that I was at one time the only medical officer of a ship cruising in northern Europe with 800 men on board. We were ordered in haste, by way of the Mediterranean, through the tropics, to northern China, to participate in the relief of Peking. Later, in the same ship, with one assistant, we carried between 900 and 1,000 men from the West Indies to the Asiatic Station. There is a lot of professional work in that sort of service.

It has been said, too, that our field of work at sea is narrow. That has not been my experience. My last sea service was on the battleship *Oregon*, both on our western coast and in China, with 550 men on board and no assistant. In order to emphasize the fact that our work may be of wide range, I have selected from the records of the *Oregon* ten cases which were treated by me to convalescence on board that ship, with but two exceptions—one a case of diphtheria, the other a case of tuberculosis; both were transferred to hospitals. The period covered was six months, and the ship cruised from Puget Sound, Washington, to Hong Kong, China, by way of San Francisco, Honolulu, across the Pacific to Yokohama and Shanghai. The cases were: two of lobar pneumonia, one of fracture of the skull with extensive facial laceration, one of smallpox, one of severe complicated typhoid fever, one of fracture of the tibia, one of malarial fever, plasmodium demonstrated in the blood; one of filariasis, with hematuria and chyluria, filaria nocturna demonstrated in the blood; one of tuberculosis, tubercle bacilli demonstrated in the sputum, and one of diphtheria, diagnosis confirmed on shore. I doubt if any one present, in his individual practice, covers a wider field than the foregoing. The proper diagnosis of some of the cases called for the use of considerable microscopic and bacteriologic technic.

The modern battleship is a floating fortress and machine shop in one. Her men and stores are handled in small boats, and she is frequently coaled from lighters; in her double bottoms poisonous gases are sometimes developed, and have to be guarded against. The naval surgeon must at all times be prepared to meet the emergencies of these hazardous conditions. He must, too, be prepared to meet the emergencies of battle, to give help to those of our own service as well as assistance to the wounded of other nations. Within a few weeks Surgeon H. D. Wilson, of the *Vicksburg*, did excellent work among the Russian wounded after the naval battle off the coast of Korea.

The handling of epidemics in the Navy is a credit to the service, notwithstanding the recent unfavorable comment of a misinformed journal. We have to deal with young recruits, many of them fresh from rural districts where the diseases of childhood are practically unknown; and sooner or later in the Navy they go through the whole list of them.

While cruising our field of work often extends beyond the limits of the ship in which we are serving. For instance, I have removed huge scrotal tumors due to elephantiasis in Samoa, have resected intestine at Guam, and have performed celiotomies in Japan. In this connection I beg leave to state that my surgical experience in the tropics bears out the statements of Major Bannister of the Army, in his recent interesting report of operative work in Manila. The successes and failures are due to the same causes that operate for good and for bad in other climates, and the results are but little, if at all, affected by tropical conditions. This is contrary to common belief. Tetanus infection is, however, a real danger in the tropics, which must be carefully guarded against. Bannister lost one case from this cause in Manila; about 15 years ago I had a similar experience in Samoa.

You will say at once, if naval surgeons have access to so much and such varied clinical material, why have we not heard more of their work? That is not difficult to understand when you realize that we work almost entirely alone during our careers in the service. There is little chance of getting together. We serve for brief periods in many localities, and about the time we are becoming identified with one community we are shifted to another. On account of the shortage of medical officers and the enormous growth of their work of late there has been little chance to specialize in the Navy. After making the required official reports and keeping the records of the service, the impulse to publish our interesting cases for the benefit of the medical profession, from which we have been more or less cut off, soon vanishes. There is another side of it, too. Some years ago I reported from Japan the history of a case of strangulated hernia, large and of long standing, which I had operated on successfully, and was rather proud of "topping off" with a method of radical cure which bears the name of a distinguished American surgeon. When I returned to New York shortly afterward, I found my surgical friends there engaged in "Bassiniizing" recurrences after the method I had practiced in Japan. You must admit that by unremitting work alone can you who live in the midst of it all, keep pace with the wonderful strides of the present day. Can we, then, be censured for hesitating to contribute to medical literature from remote corners of the earth?

The opportunity to acquire fame in the medical profession in the Navy comes to but few, but so that opportunity comes to but few, relatively, in civil life. We may be doing the same sort of work in the Navy as you are doing in civil life, but our work is confined to a feeless class, and that class, in my experience, is not, as a rule, a grateful one. The work that you do is seen by your colleagues, who seek your help, and afterward the grateful patients spread your reputations abroad, and otherwise substantially add to your well being. Not so with us. The most brilliant treatment is taken as a matter of course; if the treatment is not quite brilliant in its effects, the patients, unhappily for us, live on in the service to the end, and we can not shake them off.

The chairman of one of our most important sections I took on his first ambulance call in New York just 21 years ago. There are several other gentlemen present to-night with whom I served as interne in other hospitals. They are all well known to you, their reputations are national, while I, who have been working along the same lines all these years, am unknown outside the Navy, and in it am but one of a large number who are doing the same class of work.

It is not my intention to paint the naval surgeon's life in sombre hues; far from it. After all, it is not the big fees and the fame that hold us to our work in medicine. Both may be comforting in their way, still it is the consciousness of duty well done, the masterful handling of the sick, the planning and carrying to a successful termination of a difficult operative procedure, the skillful diagnosis and the cleverly applied treatment, they are the real rewards—they alone keep our enthusiasm aflame.

Our progressive Surgeon General has done all in his power to place every instrument and appliance of modern medicine within our reach, and if we fail to properly utilize the material the service presents it is entirely our own fault.

We are not altogether neglected in a pecuniary way. Our pay is sufficient to allow us to live in a modest, unpretentious manner, and may be considered satisfactory. In addition, in case we are disabled at any time during our careers in the Navy we may be placed on the retired list, where we receive three-quarters of the highest pay of the grade in which we are serving, and that for as long as we live. That, gentlemen, is a comforting fact, not generally appreciated outside the service.

We enter as assistant surgeons with the rank of lieutenant, junior grade, and may advance to the rank of rear admiral while filling the office of surgeon general. The rank of medical officers is positive and carries with it all the military honors that go with rank in the other branches of the service.

In my endeavor to stimulate your interest in our corps I have cited some of my own experiences. This I have done because they are average experiences and are, naturally, those with which I am most familiar.

We are sadly in need of your help to properly accomplish this great increase of our corps. Our examining board in Washington is rather remotely located, so far as the great medical centers are concerned, which accounts to a great extent for the indifferent material that appears before it. Out of ten candidates examined recently but one was successful. The examination for entrance is comprehensive but extremely practical. The literary and scientific requirements can be mastered by any one with a good common school education well in hand; in fact, any well-equipped physician, up to the physical standard, should be able to secure a commission.

In trying to keep within the alloted time I have had to pass over may interesting features of naval life. The travel incident to cruising is a never-ending source of profitable enjoyment. Courtesies, which seldom fall to the lot of the civilian traveler are extended to naval officers wherever they may be. Contact with the representatives of other nations at home and abroad adds a novel charm to the life. A cursory study of military law is demanded in order that we may act intelligently while serving on courts martial. To harmoniously and efficiently perform our multifarious duties we must acquire a knowledge of ships, of the principles of their construction and ventilation, as well as a knowledge of the purely military side of the service. You can readily see that to properly perform the duties of the medical corps of the Navy one must be well equipped professionally and otherwise, and therefore, I repeat, that it is the best products of your schools and hospitals that we seek and no other.

Those who enter the corps after October 1 of each year are brought together at the Naval Medical School the following October for a six months' course of instruction. This course is very thorough and far-reaching and includes the hygiene of camps, ships and hospitals; tropical medicine; military and operative surgery and *x*-rays; bacteriology, animal parasitology, hematology, physiological and general chemistry; naval law; the duties of naval medical officers; tactics, signals and other branches of interest to military physicians and surgeons. With this special training for their chosen careers the graduates of this school should make a creditable showing in the Navy and elsewhere.

The medical corps of the Navy has always been active in adapting to its uses the advances of the medical profession, and the work still goes on.

I can not close my remarks on what the medical profession can best do for the Navy without expressing my appreciation of the great services that profession has already rendered us. Our cruises abroad necessitate the temporary disruption of our homes, a hardship of no mean proportions, but when sickness comes to those we leave behind the situation is demoralizing. Only those of us who have been placed in this most helpless of positions can appreciate the comfort that goes with the thought, that the best medical talent in our land can be had for the asking. For that great privilege, so willingly and so cheerfully granted at all times to us and to ours, allow me to extend to you, gentlemen of the medical profession, the thanks and gratitude of the medical corps of the Navy.

WHAT THE MEDICAL PROFESSION CAN DO FOR THE PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

SURGEON-GENERAL WALTER WYMAN.
U. S. Public Health and Marine Hospital Service.
WASHINGTON, D. C.

It is a great privilege, in response to the invitation of our President and in the presence of a great audience such as always characterizes our general meetings, to say a word for the United States Public Health and Marine-Hospital Service—a service that had its origin in 1798 and has slowly but steadily grown, as grows the tree, by putting out from time to time twigs of new duties which have developed into strong branches of public service, until it has reached its present sturdy growth, secure from any casual uprooting, and still growing. Its three hundred or more medical officers may be found in every prominent port on the seacoast, from Maine to Alaska, and on our great lakes and rivers; on the Isthmus of Panama, in Porto Rico, Hawaii and the Philippines; in Canada, British Columbia, Japan, China, India and in Europe.

In the United States you will find them administering 22 government hospitals and 125 other relief stations, extending surgical and medical relief annually to 58,000 seamen of the merchant marine; you will find them administering 37 quarantine stations, inspecting and disinfecting ships, and isolating contagion approaching from foreign shores; you will find them making visual examinations of all our pilots, rejecting 4 per cent. annually for color-blindness, examining physically the crews of life-saving stations that physical defects may not mar the glorious achievements of that great service. At every port or place on the seacoast and on the Canadian and Mexican borders, where alien immigration seeks entrance, you will find these officers examining each immigrant and rejecting those that are afflicted with loathesome or contagious disease, or whose physical condition makes them liable to become a public charge. In times of epidemic, you will find them managing with military precision detention camps, acting as experts in the detection of the disease and directing with coolness and judgment the necessary measures to prevent its spread. At this very time you may find them in certain portions of our country liable to the invasion of yellow fever, waging a prophylactic campaign, by the systematic destruction of the breeding places of the mosquitoes which convey this disease, and organizing in cities and villages local working parties to continue the work, with free distribution of literature showing its necessity and detailing its method.

In contrast to this field activity you will find them in the service laboratory established in Washington by act of Congress, delving into the cause of disease and in other branches of scientific research, or receiving instruction there in the latest scientific methods of diagnosis, to be applied later in their expert work. Thence they go by request to arbitrate local disputes as to the existence or non-existence of bubonic plague, yellow fever, smallpox or cerebrospinal meningitis; to advise with regard to the source of typhoid infection, to address societies on the prevention and suppression of disease, or to investigate some new or ill-understood malady that threatens the material prosperity as well as the health of communities.

Their laboratory work includes also the test of purity of vaccine virus and antitoxic serums, on which, and on their personal inspections of the establishments producing them, depends a granting of the license required by law.

In Canada and British Columbia they are stationed to prevent the side entrance into the United States of aliens who would be rejected for physical causes at our own ports. In Japan and China they are inspecting ships, passengers and cargoes, bound for the Pacific coast, and are pointing out to the steamship companies such immigrants as they know will be refused entrance into the United States under the immigration law. In Calcutta and Bombay, and in Naples they are exercising like supervision. All these officers forwarding periodic reports giving information concerning the sanitary conditions and epidemic diseases prevailing in these respective countries.

They are administering national quarantine in the Philippine Islands, in Hawaii and in Porto Rico. You will find them in the principal fruit ports of Central America, examining and certifying fruit vessels bound for our southern coasts, that they may not be detained on arrival with their perishable cargoes. You will find them in Cuba, stationed in the offices of the consuls at the several ports, still on guard notwithstanding the sanitary regeneration of that island. You will find them in the ports of Mexico, giving bills of health to all vessels leaving for the United States, causing a waiver of detention on arrival and thus expediting commerce. You will find them on the Isthmus, in charge of the quarantine at Panama, protecting that city and the canal zone from the invasion of yellow fever from Ecuador and of the bubonic plague from Peru or Chili; and in the ports of Ecuador and Peru, carefully inspecting or disinfecting vessels bound for the Isthmus as well as those bound for the United States. You will find them, also, in Rio Janeiro and La Guayra, Venezuela, for the exercise of these same functions.

It is a world service—its influence being felt in all civilized countries.

Now, who are these medical officers? They belong to the medical profession of the United States and are its product. There are before me many of their instructors. Safe to say, there is not a medical college represented at this meeting of the Association which is not also represented in this medical corps. These officers have entered the service without political backing, on their merits as decided after thorough physical and professional examination as required by law, and without regard to locality or religion. They are, then, representative of the medical profession, and my first answer to the topical inquiry is that the medical profession can assist the Public Health and Marine-Hospital Service by bearing in mind that the service is but a part of itself—its exponent in official life. It should not be regarded as a body of medical men set apart from the rest, but as an organization seeking in its peculiar field to exemplify the best thought and effort of the profession. The service must be brought in contact with and must have inspiration from the great army of medical men in the United States, who, besides their devotion to their patients and their specialities, are thinking, thinking constantly on the great problems relating to sanitation and public health the practical dealings with which, from a national standpoint, has fallen to the lot of this service.

By maintaining or increasing a high standard of professional excellence the medical profession stimulates its brothers in government service. The medical colleges will assist in perfecting corps, not only by thoroughness of medical education, but also by raising the educational standard required of matriculants. Technical education alone is not sufficient; it should be superimposed on a general education broad enough to enable the medical officer to fitly represent the general as well as the special intelligence of the American physician.

You can further help this service by appreciating its aspirations. What are its aspirations? And what are the agencies through which they may be gratified? First, may be mentioned perfection of organization. As organized effort is superior to individual effort, so is legal organization in the long run more efficacious than voluntary. In a law passed two years ago our organization was expanded. This expansion is in line with the expressed will of the Association at its meeting in Atlanta in 1896. The new law brings us in association, so far as may be under the constitution, with the several state boards of health. Special conferences are provided for on request, and an annual conference is made obligatory between the Public Health and Marine-Hospital Service and representatives of the state boards of health. Two annual conferences have been held, resulting in a feeling of harmony and co-operation and giving promise of wide and practical results. As these state boards of health have their relations with the county and municipal boards, the latter also have an indirect relation with the national service, and the medical profession can materially assist this service by giving aid to state boards of health and local health officers as well. Many state health officers require help in securing proper legislation, and local boards of health require the aid of the profession in support of the proper functions of their office and in making the office itself so potential, with such a length of tenure, and with such adequate compensation, as to make it attractive to the most competent physicians in the community.

With this organization, to be developed and strengthened as the years go by, it is not too much to assume that general sanitation will be advanced to a degree now thought scarcely possible. The profession can further assist the Public Health and Marine-Hospital Service in its broadened scope as thus outlined, by encouraging all educational efforts in behalf of sanitation, by supporting the auxiliary sanitary associations, which I am pleased to say exist in so many states and localities, seeking to arouse from a disgraceful torpor the interest of those who are affeced by sanitation, and by creating a public sentiment which will demand an application of knowledge drawn from scientific observation, knowledge which is far in advance of its practical utilization.

One of the aspirations of this service is a slumless country. I know that this will fall on doubting ears, but I assert that there is no adequate reason why slums should exist anywhere, and by slums I mean places where, through bad drainage, imperfect sewerage, inadequate air-space, lack of pure water, and lack of sunlight, human beings are subject to disease and crime-inducing conditions.

In conclusion, in answer to the question, "What can the medical profession do for the United States Public Health and Marine-Hospital Service?" the reply may be summarized as follows: The profession can aid us by regarding us as a part of itself; by supporting us in any laudable efforts for legislative growth; by requiring a sufficiently broad education, in addition to professional excellence, of the graduates from whom we recruit our ranks; and by sympathetic support in our aspirations, which are the same as those of the profession itself.

*Symposium on Scientific Research by the Government.**

WHAT THE MEDICAL PROFESSION CAN DO FOR THE BUREAU OF ANIMAL INDUSTRY.

D. E. SALMON, D.V.M.,
Chief of the Bureau of Animal Industry.
WASHINGTON, D. C.

I desire to express my profound appreciation of the great honor which the American Medical Association has conferred on me by inviting me to address this assemblage and present my views on the subject of what this Association can do for the Bureau of Animal Industry. Having organized this bureau and directed it for about twenty years, I am naturally anxious not only for its present success and usefulness, but for its permanency and continued development. It is, therefore, with much gratification that I observe the interest which this Association is taking in the bureau and its work, as shown by your program and also by the complimentary and encouraging address on this subject which has been made by one of your able and distinguished members—a man whose ability, learning and indefatigable work have caused him to be recognized as an authority in every land where the science of medicine is known or studied.

The Bureau of Animal Industry has had a very rapid growth, and has received encouragement and support to an extent which has appeared truly marvelous at times, especially when we consider the large commercial interests which it necessarily encounters, and which it attempts, more or less successfully, to guide according to sanitary principles. However, there is no human institution so strong that it can be said to receive all the moral and material support which it requires for its highest ideals, and few which have the power to perform their ordinary duties without embarrassments, compromises and delays which might easily be avoided if they were impregnable to the attacks of their enemies and were given means commensurate to their tasks. Even the strongest governments of the world must occasionally seek the good-will and assistance of other governments. How evident it is, therefore, that an institution like the Bureau of Animal Industry must need all the aid and encouragement which those interested in its work can give it.

The American Medical Association is well known to be one of the strongest organizations in the country; and not only is it strong in its membership, but in its standing, influence, intelligence, and ability to impress its views on the people. It has the power to accomplish much—far more, I think, than most of its members realize—for the advancement of the objects in which it is interested, and in the way of influencing the sentiment and activities of the nation. There is, consequently, every reason why I should feel gratification and pride at the attention which you are giving to my work, and why I should welcome with the utmost cordiality your proffered good-will, endeavoring on my part to make the service over which I preside of increasing value and more and more worthy of your interest and support.

In order that you may have a clear understanding of the ways in which the bureau may be aided, it is necessary to say a few words concerning its work. The greater part of this work is essentially an effort to safeguard the supply of animal food in this country. This is accomplished by protecting the food-producing animals from the preventable diseases; by encouraging the production of such animals according to the best methods which science and art have devised, and by an inspection of meats at the time of slaughter. It is scarcely necessary to remind this audience how important an effect the food of a people must have on the public health. Even a scarcity of food soon increases the misery, the disease and the death rate; but when, in addition to being scarce, the food is of poor quality and unwholesome, the effect on the consumers becomes all the more apparent. There can be no doubt, it appears to me, of the very great desirability, from the sanitary point of view, of preventing diseases so far as possible among such animals, and of prohibiting the sale for food purposes of the meat of those animals which are seriously diseased. This is strictly sanitary work; it is work along the same lines that the medical profession is following, and its objects are the same as those for which you are striving.

To prevent the importation of contagion, we have inspection and quarantine of the animals that are brought here from foreign countries. To prevent the spread of our indigenous diseases, we have inspection of the animals going from an infected state to other states of the Union; we also have supervision of the stockyards and stock cars, and in this work we seize and quarantine diseased animals, disinfect cars and pens, and even prohibit the shipment of certain classes of animals in times of special danger. To guard against unwholesome meats, we have inspection before the animal is killed and again at the time the carcass is being dressed, and the meat of diseased animals is condemned and so treated that it can no longer be used as food. Under the present conditions of producing meat such a system is absolutely necessary for the protection of the consumer; for how can the purchaser of meats know the condition of animals which he has never seen—animals which were raised, perhaps, on the western plains, which were slaughtered in Kansas City by he knows not whom, and the meat of which has passed through channels which it is difficult to retrace.

There are now inspected annually at the time of slaughter about thirty-seven million carcasses of cattle, sheep and swine, and out of this number it was necessary to condemn last year sixty-five thousand entire carcasses, and parts of sixty-four thousand other carcasses. This great quantity of unwholesome meat was, therefore, taken out of the trade and safely disposed of by the inspection service. In addition to this meat inspection, eighteen million animals from infected districts were inspected and shipped under supervision, and sixty-six thousand infected cars were disinfected.

It is not my purpose to tire you with statistics or with details concerning this work, but I do hope to impress you with its objects, magnitude and scope, in order that you may appreciate the difficulties and obstacles which are constantly arising. No one can condemn and destroy sixty-five thousand carcasses of meat without causing many protests and arousing much opposition; no one can hold thousands of railroad cars and require their disinfection without meeting with obstacles and trouble often beyond what is anticipated; no one can go into a state and control its animal traffic, enforcing the more or less arbitrary and burdensome restrictions which are required to stamp out disease, without the strongest influence being brought to bear from time to time against the enforcement of such regulations. Whether or not an executive officer can maintain his regulations and accomplish the object which he

---

* Presented to the General Meeting, Thursday evening, June 9, 1904. See also page 1640, June 18.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION
1904-1905

GENERAL OFFICERS

PRESIDENT—JOHN H. MUSSER	Philadelphia, Pa.
PRESIDENT-ELECT—LEWIS S. MCMURTRY	Louisville, Ky.
FIRST VICE-PRESIDENT—EDWARD JACKSON	Denver, Colo.
SECOND VICE-PRESIDENT—JAMES HALL BELL	San Antonio, Texas.
THIRD VICE-PRESIDENT—F. C. SHATTUCK	Boston, Mass.
FOURTH VICE-PRESIDENT—B. C. PENNINGTON	Atlantic City, N. J.
GENERAL SECRETARY AND EDITOR—GEORGE H. SIMMONS	103 Dearborn Ave., Chicago.
TREASURER—FRANK BILLINGS	Chicago.

BOARD OF TRUSTEES.

E. E. Montgomery, Secretary, Philadelphia, 1905.
H. L. E. Johnson, Washington, D. C., 1905.
H. L. E. Johnson, Washington, D. C., 1905.
William H. Welch, Baltimore, 1906.
Miles F. Porter, Ft. Wayne, Ind., 1906.
M. L. Harris, Chicago, 1906.
W. W. Grant, Denver, 1907.
T. J. Happel, Chairman, Trenton, Tenn., 1907.
Philip Marvel, Atlantic City, N. J., 1907.

JUDICIAL COUNCIL.

P. Maxwell Foshay, Illinois.
George Ben. Johnston, Virginia.
D. C. Peyton, Indiana.
W. B. Russ, Texas.
F. H. Wiggin, New York.

COUNCIL ON MEDICAL EDUCATION.

W. T. Councilman, Massachusetts.
Victor C. Vaughan, Michigan
J. A. Witherspoon, Tennessee.
Arthur Dean Bevan, Illinois.
Charles H. Frazier, Pennsylvania.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Richard C. Cabot, 190 Marlboro St., Boston; Secretary, J. L. Miller, 100 State St., Chicago. Executive Committee—Frank A. Jones, Memphis, Tenn.; W. S. Thayer, Baltimore; Alexander Lambert, New York City.

OBSTETRICS AND DISEASES OF WOMEN—Chairman, C. L. Bonifield, 432 West Fourth St., Cincinnati, Ohio; Vice-Chairman, F. F. Lawrence, Columbus, Ohio; Secretary, W. P. Manton, Detroit, Mich. Executive Committee—J. H. Carstens, Detroit, Mich.; A. Palmer Dudley, New York City; L. H. Dunning, Indianapolis.

SURGERY AND ANATOMY—Chairman, Maurice Richardson, 224 Beacon St., Boston; Secretary, Floyd W. McRea, Atlanta, Ga. Executive Committee—DeForest Willard, Philadelphia; James E. Moore, Minneapolis; Charles A. Powers, Denver, Colo.

OPHTHALMOLOGY—Chairman, C. R. Holmes, Cincinnati, Ohio; Secretary, W. L. Pyle, 1806 Chestnut St., Philadelphia. Executive Committee—Frank Allport, Chicago; John E. Weeks, New York City; Robert L. Randolph, Baltimore.

HYGIENE AND SANITARY SCIENCE—Chairman, John S. Fulton, 1809 St. Paul St., Baltimore; Secretary, M. L. Price, 1532 Linden Ave., Baltimore, Md. Executive Committee—Arthur R. Reynolds, Chicago; H. M. Bracken, Minneapolis; G. T. Swarts, Providence, R. I.

DISEASES OF CHILDREN—Chairman, John Lovett Morse, 70 Bay-State Road, Boston; Vice-Chairman, W. E. Darnall, Atlantic City, N. J.; Secretary, J. Ross Snyder, Birmingham, Ala. Executive Committee—H. M. McClanahan, Omaha; John C. Cook, Chicago; Charles G. Kerley, *New York City.*

STOMATOLOGY—Chairman, Vida A. Latham, Rogers Park, Ill.; Vice-Chairman, Edward C. Briggs, 129 Marlboro St., Boston; Secretary, Eugene S. Talbot, 103 State St., Chicago. Executive Committee—A. H. Peck, Chicago; M. L. Rhein, New York City; G. F. Eames, Boston.

NERVOUS AND MENTAL DISEASES—Chairman, J. H. McBride, Los Angeles, Calif.; Secretary, David I. Wolfstein, 22 West Seventh St., Cincinnati. Executive Committee—Richard Dewey, Wauwatosa, Wis.; F. W. Langdon, Cincinnati; H. T. Pershing, Denver.

CUTANEOUS MEDICINE AND SURGERY—Chairman, Douglas W. Montgomery, 1301 Van Ness Ave., San Francisco; Secretary, R. R. Campbell, 204 Dearborn St. Chicago. Executive Committee—Henry W. Stelwagon, Philadelphia; John A. Fordyce, New York City; Henry G. Anthony, Chicago.

LARYNGOLOGY AND OTOLOGY—Chairman, Robert C. Myles, 46 West Thirty-eighth St., New York City; Secretary, Otto T. Freer, 288 Huron St., Chicago. Executive Committee—G. Hudson Makuen, Philadelphia; George L. Richards, Fall River, Mass.; John F. Barnhill, Indianapolis.

PHARMACOLOGY—Chairman, Heinrich Stern, 56 East Seventy-sixth St., New York City; Secretary, C. S. N. Hallberg, 358 Dearborn St., Chicago. Executive Committee—George F. Butler, Alma, Mich.; Solomon Solis-Cohen, Philadelphia; O. T. Osborne, New Haven, Conn.

PATHOLOGY AND PHYSIOLOGY—Chairman, Winfield S. Hall, 2421 Dearborn St., Chicago; Secretary, Henry A. Christian, Boston City Hospital, Boston. Executive Committee—Frank B. *Wynn, Indianapolis; Victor C.* Vaughan, Ann Arbor, Mich.; Joseph McFarland, Philadelphia.

GENERAL INDEX.

The general index includes references to all the reading matter that has appeared in the pages of The Journal for the past six months. Use of the index will be facilitated by bearing in mind that subjects are frequently given under two or more headings; for example, brain, cerebral, tumor, etc.; heart and cardiac; cirrhosis, liver, hepatic, etc. Often, too, writers treat of the eye, ear, nose and throat under one title. There is no longer a department index such as used to follow the general index, but all the "Deaths" are together at the end of the letter "D." Similarly, all societies are under the heading of "Societies" at the end of the letter "S." All matter pertaining to the American Medical Association is placed together under "Association News." All books are listed under "Book Notices." The following letters are used to indicate the nature of the matter referred to: "E" indicates an editorial, "O" original article, "T" therapeutic item, "Ml" an item in the medicolegal department, and "ab" an abstract of an article that has appeared in full elsewhere. The titles and authors of the articles which are listed each week in other journals are given under the Current Medical Literature Index on pages 1724 to 1755.

ASSOCIATION NEWS.

Address of President to House of Delegates, 1574
Addresses of Welcome, 1647
Atlantic City as a resort, 1156
  City Hotels, 388, 912
  City profession, welcome from, 1647
Attendance, 1572
Branch Associations, report on, 1639, 1645
Bureau of Animal Industry, 1649
  of Chemistry and Medical Science, 1649
Canadian Association, greetings from, 1643
  Cancer Research, 1644, 1645
Clinics at Philadelphia, 1093
Committee of Arrangements, report of, 1647
  on Award of Senn Medal, report of, 1576
  on Hygiene, report, 1640, 1645
  on Legislation, report of, 726, 1165, 1577, 1644
  on Medical Education, report of, 1576
  on National Incorporation, report of, 1581
  on Organization, 1579, 1640, 1645
  on Portraits of ex-Presidents, report of 1648
  on prize essay, report of, 1576
  on Prophylaxis of Venereal Diseases, report of, 1641, 1645
  on Reapportionment, report of, 1644, 1646
  on Reciprocity, report of, 1644
  on Rush Monument, report of, 1576, 1640, 1643
  on Scientific Exhibit, report of, 1644, 1645
  on Scientific Research, report of, 1643
  on Sections and Section Work, report of, 1580, 1640, 1644, 1645
Committees, list of, 1165, 1646
  reference, 1576
Constitution, amendment of, proposed, 1643, 1646
  and By-laws adopted, new, 1634
Daily Bulletin, the, 1573
Delegates to International congresses, 1644
Entertainments, 1573
General meetings, 1572, 1647
Government services, symposium on, 1648
House of Delegates, 1438, 1507
Journal clearing house commission, 1576, 1644
Judicial Council, report of, 1646
Laryngology guest at Atlantic City, 607
  study station advised, 1644, 1645
Mails, resolution on purification of, 1643
Map of Atlantic City. 1307
Materia Medica section, proposed change of name, 1646
Medicine and Food Bureau, report of, 1640, 1644
McMurtry, Lewis S., President-elect of the Association, 1632
Musser, President, address at unveiling of Rush Monument, 1633
National incorporation, 1634
New members, 114, 481, 727, 969, 1308, 1649
  York Society members, privileges extended to, 1643
Ophthalmology papers illustrated, 1372
Orations, 1540, 1545, 1550
Organization meeting called, 1166, 1372
Philadelphia Clinics, 727, 1172
Place of session for 1905, 186, 257, 1645
Place of sessions, presidents, vice-presidents and Orations of American Medical Association for past fifteen years, 1575
President, report of, 1639
Railroad rates, 1371, 1437
  tickets, deposit of, 1507
Ramsay, Professor, to be guest of Section on Ophthalmology, 1037
Reed memorial fund, 1572, 1643, 1647
Registration, 1438, 1507, 1626
Roosevelt, President, address at unveiling of Rush Monument, 1634
Rush Monument announcement and picture of statue, 1164, 1237
  Monument, unveiling exercises, the. 1633
Scientific exhibit, 1307, 1507, 1645
Secretary's report, 1575, 1639
Section meetings, 1572
  preliminary programs, 1166
Sims, Marion, presentation of portrait of, 1648
Symposia, 1648
Time of meeting of state associations, report on, 1639, 1645
Treasurer, report and resignation of, 1634
Trustees, status in House of Delegates, 1644, 1645
  report of Board of, 1634, 1645
Venereal diseases, publications on, 1644
  diseases, resolution on prophylaxis of, 1645
Wilson, J. C., oration at unveiling of Rush Monument, 1634
Wood alcohol as a dangerous poison, resolution on, 1643, 1644

B

Baccelli, retirement of, from Italian cabinet, 320

CURRENT MEDICAL LITERATURE

INDEX OF TITLES

Explanation: This index includes the titles and the subjects of original articles published in the leading medical journals of the world during the past six months. The titles and the names of the journals in which they appeared were published weekly in the Current Medical Literature department, to which references are made. The figures in parentheses refer to the paragraph; the number following, to the page in The Journal. For instance, "Abdomen, acute diseases of the, (57) 1450—ab," refers to page 1450 of The Journal, on which is found opposite paragraph 57 the title of the paper and the name of the author, viz.: "Diseases of the Abdomen, Carl J. Holman." This title is listed under the journal in which the article appeared, "St. Paul Medical Journal, May." The "ab" indicates that an abstract of the article appeared in The Journal, which will be found below the title. Titles of articles which appeared in The Journal are indicated in the index below by an asterisk (*) before the page number. Index to authors of all the articles below is on pages 1756 to 1770 of this index. The reading matter which appeared in The Journal is indexed in the General Index on pages 1703 to 1723.

A

domen, acute diseases of the, (57) 1450—ab
  agnosis in right half of, (118) 402
  gunshot wound of, (72) 1254
  normal pylorus and phantom tumors in, (63) 342—ab
  regions of, from surgeon's standpoint, (98) 492
Abdominal and pelvic surgery without ligatures — electrothermic hemostasis, (62) 1663
  cavity, illumination of, (67) 807—ab
  conditions, some deceptive, and question of operation, (7) 683—ab
  contusions, (102) 739, (108) 981
  incision, technic of, (66) 807
  operations, peritoneal saline infusions in, *281
  operations during pregnancy, (137) 1453
  pain, (101) 1388, (89) 1595
  pain and pneumonia, *709, *1492
  pain in acute rheumatism, (2) 1521—ab
  pain of intestinal origin, (8) 612—ab
  pain, significance of, (109) 1520
  (parietal) incision, choice of methods for closing, (76) 1105
  pregnancy, (79) 930
  pulsation, autopsy findings in case of, (147) 925
  section during pregnancy, six cases of, (75) 1105
  section, preparation of patient for, (30) 398—ab
  sections, 117 (82) 338
  supports, (119) 137
  surgery, case or two in, (130) 1388
  surgery, local cocain in, (33) 1454—ab
  surgery, practical points in, (2) 974—ab
  surgery, unsettled questions in, (72) 1594—ab
  surgical disease, some cases of chronic, (82) 408—ab
  traumatism, two cases of, (22) 397
  troubles, early operation in, (21) 397—ab (93) 1320
  tumors in children, diagnosis of, (65) 1663
  viscera, death from lesions of, (99) 924
  wall, transplantation of muscle to close defects in, (113) 1260
Abnormal children in Italy, (96) 617
Abortion, artificial, (122) 561
  criminal, (105) 339
  forceps, (70) 134
  histologic diagnosis of, (96) 344
  inevitable, proper treatment of, in its relation to uterine disease, (97) 981, (104) 1388
Abortion, instruments for production of, sold in market places of Paris, (19) 488—ab
  methods of provoking, (110) 566
  remarks on, (115) 801
  treatment of, (83) 209, (135) 1051, (119) 1327
  tubal, extrauterine pregnancy with reference to, (27) 267
Abscess, cerebral, case of, (107) 492, (14) 683
  extradural and mastoid disease, (45) 616
  hepatic, ascites and gallstones, operations for, (24) 205
  otitic cerebellar, case of, (141) 567
  perineal, and diffuse phlegmons of urethral origin (31) 684
  peritonsillar, (82) 561
  prostatic, (80) 129
  retroperitoneal, (96) 682
Absinthism in France, (82) 1664
Absorption, inhibition of by adrenalin, (73) 987—ab
Academies for practical medicine, (63) 985
Academy, Duesseldorf, for post-graduate instruction, (22) 1698
Accessory cavities of the nose improvements in treatment of chronic suppurations of (65) 61—ab
  nasal cavities, diseases of, (47) 1385
  sinus disease, observations on treatment of, (128) 561
  sinuses, (42) 1317—ab
  sinuses of nose, symptoms and diagnosis of suppurative diseases of, (85) 1595—ab
  sinuses of nose, treatment of suppurative diseases of, (83) 1595—ab
Accident insurance decisions medico-legal, (52) 1111
  cases, our relation in, (69) 1386
Acetanilid, therapy of, (12) 1514
Acetic acid in diseases of nose and throat, (107) 1520
Acetone fermentation, (112) 988
Acetozone in otology and rhinology, (40) 1251—ab
Achilles tendon covering for stumps, (84) 1457—ab
Achlorhydria, six cases of, (33) 59
Achylia and peritonitis with adhesions consecutive to contusion of abdomen, (109) 809
Acid bacilli, actual and comparative resistance of, (72) 858—ab, (128) 981

  stomach from observation of 23 operations, (16) 273
  stomach, success of thiosinamin and massage in cure of, (116) 1327
Houston's sewage streptococci, cultural relations and antagonisms of Bacillus coli and, (46) 336
Human actinomycosis, differential diagnosis of (30) 1322—ab
  bile in gall bladder, (57) 1257
  blood, Arnold de Villa Nova on therapeutic use of, (35) 274
  blood biologic test for, (131) 1320
  blood new biologic test for, (25) 854—ab
  embryos value, method of preserving and sectioning, (104) 1520
  sera agglutination of streptococci especially those cultivated from cases of scarlatina by (40) 335
  viscera, dislocation of growing importance of possibility of, (100) 682
Humanity and medicine the two sciences, *1263
Humerus case of backward dislocation of head of, (12) 740
  fractures of balancing suspension treatment of (41) 621
  fracture of in child in its delivery (125) 1051
  in childhood injuries to lower end of, (147) 618
Humors dynamic properties of, (27) 803
Hunger, psychology of (21) 796
Huntington's chorea, case of, (12) 1179
Hutchinson's teeth in inherited syphilis (73) 1057—ab
Hydatid cyst, fatal intoxication from rupture of (65) 624
  cysts in brain prognosis of (117) 566—ab
  cysts of broad ligament and greater omentum, (22) 562
  disease in Egypt, note on rarity of (23) 1322
Hydatidiform mole, (131) 1254
Hydramnion, experimental production of (55) 1324
Hydrencephalocele sagitalis birth mechanism in cases of, (87) 1393
Hydrocele funiculi bilocularis extra et intra abdominalis (134) 746
  Rholdan's method of treating, (152) 690—ab
Hydrocephalus, congenital, chronic, cure of, (90) 1526
  internal, in youth, case of chronic (65) 737
Hydrocephaly, (98) 1193
Hydrochloric acid, effects of drinking 25 c c of, (15) 620
Hydrography, subterranean, studies of, (21) 983
Hydrologic scale (113) 745
Hydronephrosis due to abnormalities in ureters, (11) 1388
  intermittent, (18) 334
  intermittent combination of, and enteritis, (32) 1665—ab
Hydronephrosis, traumatic, (138) 346—ab
Hydrophobia, Chinese remedy for, (11) 1522—ab
  treatment of, (91) 987—ab
  with autopsy, case of, (82) 401
Hydrophthalmus, acquired, (6) 1045
Hydrotherapeutic prescriptions, (30) 1046—ab
Hydrotherapy, (62) 1183
  electricity and massage in treatment of diseases of children, (35) 679
  in typhoid fever, (114) 63
  physiologic and clinical aspects of, with reference to treatment of psychoses, (25) 975
Hygienic Laboratory of Public Health and Marine-Hospital Service, research work in, *1686
Hygienics from Colberg, (100) 931
Hygroma of deep trochanteric bursa, (52) 341—ab
Hymen intactus, significance of, in medical jurisprudence, (148) 130 (51) 336—ab
Hyoscin hydrobromate in morphin habit (80) 62—ab
Hyperacidity and hypersecretion, (20) 1698—ab
Hyperalgesic zones in neck after bullet wounds of head, (31) 1598
Hyperchlorhydria, (16) 1052
Hyperchloruria in tuberculous pleurisy, (30) 563—ab
Hyperemia improved apparatus for inducing, (81) 807—ab
  of extremities (erythromelie), chronic symmetrical diffuse, (53) 1253
  therapeutic venous, technic of, (63) 1191—ab
Hyperemesis gravidarum (92) 129 (65) 807—ab, (81) 930
  gravidarum nux vomica and soda in (44) 804
Hypernephroma of kidney, (87) 1595
Hyperpyrexia, case of extreme, (81) 408
Hypersecretion and hyperacidity, (20) 1698—ab
Hyperthermia metabolism in, (79) 1525—ab
Hypertrophy of lower extremity, congenital (36) 921
  prostatic choice of operation for (26) 1316—ab
  prostatic study of 200 postmortem specimens of, (63) 980—ab
  prostatic surgical problem in, (91) 338—ab
  prostatic, 200 postmortem specimens of, (105) 1320
Hypnosis in incurable organic disease, (180) 279—ab
  in therapeutics, limitations of, (81) 209
Hypnotic action, mechanism of (122) 745
  therapeutics, experiments and conclusions in, (23) 125
Hypnotics modern (54) 1663—
  study of (130) 63
  use and abuse of, *1335
Hypnotism, medicolegal facts in practice of (115) 682
Hypnotized dancer, the, (114) 1326—ab
Hypochlorhydria nervosa, (75) 800—ab
Hypochlorous acid powerful disinfectant action of, (74) 1457—ab
Hypodermatic medication in Italy, (28) 678—ab
Hypodermic injection, apparatus for using rubber elasticity in (12) 493
Hypodermoclysis, submammary, unusual sequela of, (19) 556
Hypohemia in the tropics, (85) 1057
Hypophysis tumor relations with acromegaly, (41) 1523
  tumors of the, (137) 1395—ab
Hypospadias Beck's operation for (37) 615—ab, (96) 744
  suggestion in operations for, and method to prevent closure of nares in rhinoplasty, (97) 1185
Hypotension chronic arterial, (2) 618
Hysterectomies, five successful, for fibroid disease in one family, (3) 683
Hysterectomy, abdominal, technic of, (36) 741
  abdominal vs vaginal, (22) 557, (56) 558—ab
  for infectious disease of the uterus and uterine appendages, (7) 197—ab, (69) 1318
  of a gravid uterus complicated by fibroids, (116) 1595
  some cases of (16) 205
  subtotal abdominal, (35) 1666
Hysteria, (106) 1107, (135) 1388
  and female sexual organs, relations between, (64) 807—ab
  and organic disease, (27) 1180
  certain manifestations of, (92) 1595
  in organ of hearing, manifestation of traumatic, (70) 400
  (traumatic neurosis), severe case of major following accident, (28) 1447
  traumatic, with twilight conditions and inappropriate answering, (81) 343
  true and false stigmata of, (102) 931
Hysterical hyperpyrexia and hemoptysis, case of, (148) 1521
  skin symptoms and eruptions, (136) 567—ab
Hystero neuroses and their relation to physical examination of all women patients, (29) 1448—ab
Hysteropexy by suspension of round ligaments (74) 685
Hysterotomia vaginalis anterior (135) 346
Hysterotomy, exploratory, (22) 493—ab

I

Ichthyol compounds, therapeutics of, (19) 926—ab
Ichthyosis atypical lesions in, (91) 617
  case of local symmetrical, (170) 279
Icterus in secondary syphilis, (49) 1593
  lithogenous, case of, (5) 1591
  nature of crystals in feces of, (106) 1326
  neonatorum, (109) 1320
  neonatorum, fatal, (27) 340
Ideo obsessional constitution, differential diagnosis in cases of, (94) 617
Idiocy, (25) 984
  and imbecility, contribution to etiology of, (13) 1383—ab
  case of amaurotic family, (91) 1320
Ileocolitis (100) 1520
  in children, clinical aspects of, (36) 1449—ab
Ileus, (64)1524—ab
  atropin and (67) 1667
  diagnosis of site of occlusion in, (52) 206—ab
  from complication of pregnancy with ovarian cyst, case of, (159) 279
Iliac artery, intraperitoneal compression of, (91) 744—ab
  artery, ligature and compression of, (92) 744—ab
Illegitimacy an economic problem, *1135
Imagination, use and abuse of in experiments and observations in medicine, (7) 1045
Immune bodies attempt to explain mode of action of, by physical properties (81) 275
  bodies, significance of peculiarities and mode of action of (66) 1056
  bodies, study of (58) 1391
  serum, action of certain salts on complement in, (42) 336
Immunity and treatment, (23) 132
  against acute infections, (154) 138
  anti bacterial (155) 138
  influence of drugs in inducing (36) 1256—ab
  introduction of modern theories of (22) 1256
  passive, (128) 688
  points in modern theories of, (56) 1253
  theory of natural antibacterial (53) 561
  rôle of internal organs in production of, (182) 280

catheterization, problems of technic of, *1476
stone, ureteral injection of oil followed by spontaneous passing of, *708
Ureter cystoscope in treatment of diseases of renal pelvis and ureter (1) 611—ab
Ureterocystostomy for accidental wound of ureter in vaginal hysterectomy, (45) 1662
Ureterotome, new modification of the by Maisonneuve, (10) 1697
Ureters bilateral duplication of *1354, (70) 337
complete duplicate, distal termination of, (93) 981
in bladder, bilateral implantation of, (50) 1055
surgery of the, (122) 1527
Urethra, correct technic for packing the, in gonorrhea, gleet and stricture, (6) 1446

Urethra, electrolytic dilatation of, (26) 684—ab
female, ablation of, (14) 562
perineal, suprapubic incision as means of locating, (45) 679
Urethral catheterization and urine separation, with hemocryoscopy and urinocryoscopy in surgical diseases of kidney, value of, (22) 125—ab
injections, importance of separation between anterior and posterior urethra, (53) 494
injections, technic of, (28) 684
labia or urethral hymen, (3) 732—ab
obstruction and vesical calculi, cases of, (74) 492
stricture, cases of, (35) 977
strictures, treatment of, (78) 401—ab
thritis, blenorrheal, (18) 562
norrheal, Janet method of treating, (30) 684—ab
treatment of, (35) 398—ab
rethroscopy, limitations of practical value of, (99) 63
Urethrotomy by combined use of anterior and posterior sound as guides, *97
internal, (110) 618
Uric acid conditions, prophylactic treatment of, (84) 981, (141) 1453
acid, formation of, in human body, (56) 407—ab
acid in gout and lithemia, (9) 1314
acid in urine, Hopkins-Folin method for determination of, (23) 1315—ab
acid question, present status of, *431
Urinalysis in pregnancy, significance of, (57) 679—ab
questions of, bearing on diagnosis of contracted kidney, (9) 733—ab
Urinary analysis, corroborative method of, (125) 1186
analysis, few practical points on, (157) 618
apparatus, (58) 1257—ab
bladder, perforation of, by appendiceal abscess, (58) 736
cysts, (139) 801
diseases, diagnosis of, (110) 1520
Urine and apparent phosphaturia, hypoacidity of, (103) 566
and segregated urines, examination of, as means of diagnosis in surgical kidney diseases, (98) 924—ab
chemistry of, in diseases of pancreas, (12) 1108
chromatic variations in precipitated and sedimented chlorides, sulphates and phosphates of, (54) 1593, (86) 1595
divisor, interpretation of findings with, (1) 562—ab
incontinence in women, surgical treatment of acquired, (9) 333—ab
retention in tabes, (45) 1599
segregation by massage of each kidney, (7) 1697—ab
technic in routine examination of, (123) 981
tubercle bacilli in, (134) 933
Urofane, (75) 1193
Urology, French Congress on, (34) 684
Uterine adnexa, conservative surgical treatment of, (54) 558
adnexa, palliative treatment of cancer of, (55) 558—ab
curette as therapeutic and diagnostic agent, (129) 272
curettement, dangerous (?) operation of, (9) 919—ab
displacements, physiology and rationale of, (65) 1318—ab, (33) 1449—ab
hemorrhage, clinical significance of prolonged, (65) 1253
ligaments, anatomy and functions of, (67) 1318—ab
muscle, work on metritis and endometritis in relation to life history of, (27) 927
perforations, accidental, (39) 1593—ab
retrodeviations, etiology of, (155) 801
retrodeviations, non-operative treatment of, (154) 801
Uterus, accidental perforations of, *944
and vagina, aphasia of, (63) 807
Uterus and vagina, treatment of displacement of, (77) 565
bicornis, diagnostic sign of pregnancy in, (68) 685
extraperitoneal transplantation of, after enucleation of myomata and as treatment of prolapse, (80) 1257—ab
fixation in child-bearing age, (90) 1393—ab
hour-glass contraction of, (23) 677
how to treat backward displacement of, (21) 1454
imperfect development of the, (157) 1186
in mice, involution of, (127) 1527
myomatous, supravaginal amputation of, on account of pregnancy, (80) 1393
operative treatment of retroversion of, (61) 1318—ab
permanent results of operations for displacements of, (119) 1527
prolapse of, (96) 401
retrodisplacements of, (30) 126—ab
retroversion of, (140) 63
sound for perforating membranes, (67) 1667—ab
specimen of angio-myoma of, (87) 561
stretching of lower segments of, with intact fetal membranes, (60) 807
the infected, (114) 1254
treatment of retrodeviations of, (32) 921—ab

V

Vaccination, (146) 688
application, benefits and disadvantages, (105) 1185
in Bavaria, (93) 686
influence of age on susceptibility to, (144) 1396
Vaccine excitor, (75) 275
virus, commercial, bacteriologic investigation of, (13) 198
virus, objection to our present, (52) 1385—ab
virus, remarks on preparation of, (19) 853
virus, tetanus and, (61) 128
Vaccinia and vaccination, (109) 618
etiology and pathology of, (83) 1387—ab
Vagina and pelvis, illumination of, (66) 685—ab
case of absence of, with operation, (125) 925
double, with single uterus, (75) 930
hymenal atresia of, (149) 278
syphilitic alterations of, (67) 1392
Vaginal celiotomy in pelvic affections, (123) 1328
cesarean section, technic of, (72) 685
cysts, (124) 1527
drainage of abdominal cavity, advantages of, (121) 1527
injections and sulphurous acid, (31) 803
or abdominal operations in gynecology, (39) 494
outlet, relaxed, (106) 1320
section in extra-uterine pregnancy, (24) 1592
section, scope of, 69) 1594—ab
wounds from coitus, (84) 565
Vaginofixation, prevention of disturbances in delivery after, (30) 494
Vagitus uterinus, (65) 134, (69) 685, (73) 930
Vagotomy, bilateral, (65) 1113
Vagus and peritonitis, (49) 685—
experimental study of physiology of thoracic portion of, in relation to question of acute emphysema of lungs, (68) 408
Valerian preparations, alterability of, (20) 404
Validol, pharmacology and therapeutics of, (149) 801
Valsalva's experiment practical significance of, (98) 1393
Valve syringe, (156) 1396
Valvular disease of the heart, management of, (139) 1388
Varicocele, (3) 1660—ab
high operation for, (151) 1186
suspension of testicle in treatment of, (39) 1109—ab
Varicose ulcers, local treatment of, (72) 1049—ab
Varicose veins, nature and treatment of, (148) 1453
Variola and vaccinia, study of immunity in, (82) 1184—ab
bacteriolytic complement of blood serum in, (89) 1388
central nervous system in, (88) 1388
clinical observations on, (90) 1388—ab
epicrisis of papers on, (91) 1388—ab
in the monkey, experimental, (84) 1387—ab
infectiousness of blood in, (86) 1388—ab
infectiousness of late stage of skin lesion in, (87) 1388—ab
leucocyte reaction in, (85) 1387—ab
pathologic anatomy and histology of, (80) 1387—ab
Vas deferens after suture, permeability of, (43) 621—ab
deferens, anastomosis of, (36) 1455—ab
deferens, method for anastomosing a severed, (8) 273
Vascular apparatus, changes in, persisting after injuries, (51) 66
degeneration, retinal symptoms of, (20) 677—ab
system, surgical physiology of the, (48) 1317
Vasectomy, (41) 735—ab
Vasomotor center in inhibition of heart, (13) 1447—ab, (5) 1514—ab
instability in estimating significance of irregularity of cardiac rhythm, importance of considering element of, (7) 1247—ab
Veins, alterations of tunics of, in varicose processes, (77) 496
sclerosis and ossification of, (8) 1248—ab
Venereal disease, rational method for controlling spread of, (69) 1663
diseases, German circular in regard to, (58) 1189
diseases in army and navy, value of statistics in connection with, (90) 492
Venesection, use of, (131) 63
Venoms, action of, on nervous system, (23) 273—ab
Ventrofixatio uteri, cases that illustrate the disadvantages of, (76) 685
Ventrofixation of uterus, (27) 741, (3) 1051—ab
of uterus with subsequent normal deliveries, (66) 980—ab
Veratrum viride, (134) 204
viride in surgical and obstetric practice, (52) 558
Vermiform appendix, surgical relation of, to perforation in typhoid fever, *998
Vernal catarrh, (51) 1318
Veronal, (5) 860—ab, (104, 1394
poisoning, case of, (117) 498
Verruca senilis, histology of, (60) 564
Vesical calculi, (70) 560—ab
cases, three unusual, (97) 800
catarrh, obstinate, (111) 1394
concretions, fibrinous, (56) 736
irrigation by double current sound, (43) 804
neck, contracture of, (106) 925
Vesicovaginal fistulas, (88) 931
Vesicular mole, (137) 1051
mole in six months' twin ovum, (86) 1393
mole of unusual size, case of, (6) 683
Vessel crises in tabes, (79) 209
spasms, (140) 933—ab
Vienna, study of medicine in, (102) 1107
Villi, deportation of, and its consequences, (67) 685
Vincent's angina, contagion of, (51½) 274
Vinum colchici seminis, sine colchicina, (110) 1254
Violet rays, effect of, on nebulæ, (9) 975—ab
Viper bite, severe intoxication from, cured by potassium permanganate injections, (76) 1193
Viscera, behavior of, after cutting off their circulation, (74) 486—ab
congenital transposition of, diagnosed during life and demonstrated by autopsy, (68) 560
Visceral crises in erythema group of skin diseases, surgical importance of, (41) 1593—ab
inflammations, treatment of some acute, (2) 64—ab
manifestations occurring in erythema group of skin diseases, (115) 860
transposition with absence of spleen, (33) 205—ab
Vision, hallucinations of, (4) 332
neurology of, (13) 1255—ab, (10) 1321—ab
in deaf mutes, (34) 1665—ab
testing of, in public schools, (43) 558
Visual acuity in relation to working capacity, (34) 1665
disturbances in brain injury, contribution to study of, *216
requirements of engine men, (60) 737—ab
Vitiligo treated with Finsen light, (50) 336
Vital operations, physical and chemical forces in, (39) 978
statistics, collection and registration of, (71) 1049—ab
statistics, value and importance of, (101) 1107
Vitreous and aqueous bodies, phosphorated substance in, (159) 933
development and significance of, (34) 856
Vocal cords in children, spasm of, (40) 494
fremitus, some notes on, (14) 1592—ab
Volar sound, (95) 931
Volhard, reply to, (30) 405
Volume index, study of, (46) 269—ab
Volvulus and ileus from movability of ascending colon, (40) 1455—ab
occluding vagina and preventing delivery, (119) 276
of cecum, (79) 987—ab
of omentum, *767
of sigmoid flexure, (53) 66
of stomach, (35) 1317—ab, (118) 1459
Vomiting in stomach diseases, significance of, (61) 922
Von Recklinghausen, his seventieth birthday, (77) 68
Vulva, cauliflower tumors of, (51) 1524

W

Wabash Railway surgeons, history of Association of, (135) 1320
Warts, moles and other facial blemishes, removal of, (56) 857—ab
Water and air in their relation to disease, (143) 1453
and its relation to health, (139) 402
bacterial examination of 104 samples of, (53) 1593—ab
elimination of, through skin, (90) 865—ab
elimination of, through skin and lungs, (61) 1257
supplies, pollution of, (36) 856
supply for cities, potable, (134) 339
supply of Butler, Pa., cause of infection of, (121) 1107
supply of Cleveland, (69) 1519
to public health, relation of, (53) 1385—ab
treatment of depraved state of system incident to drinking of contaminated, (107) 63
Weber test for occult stomach and intestinal hemorrhages, (54) 863—ab
Weigert's method for staining medullated nerve fibers notes on technic of, (99) 561
Weil's disease in Egypt, (126) 498
Weismann, A., tribute to, on his seventieth birthday, (57) 623
Werrheim's carcinoma operation, technic of, (90) 931
West Central Africa, tropical diseases common in highlands of, (30) 741
Western clinics, the great, (93) 492
Wet-nursing and the selection of a wet-nurse, (119) 498
Whooping cough and diphtheria, hemiplegia in, (7) 925
cough, case of complete ophthalmoplegia occurring during, (7) 204

Whooping cough, changes in central nervous system in, (60) 495
  cough, cypress oil in, (126) 1327—ab
  cough, fatality of, (79) 980
  cough, pathologic anatomy of, (113) 688
  cough, therapeutics of, (44) 798—ab
Widal reaction, character of, in present epidemic of typhoid, (68) 1519—ab
  reaction, notes on, (25 489
William Pepper Laboratory of Clinical Medicine, *1678
Winterhalter's ovarian ganglion, history of, (74) 807
Wire basket for object glasses, (52) 407
  joints, (104) 566—ab
Wiring of bone for recent and ununited fracture, (15) 1101
Woman, psychologic generative cycle of, (136) 618
Women, are they fitted to work regularly, (9) 1696—ab
  brief observations on some conditions in, of much concern to practitioner, (105) 1051
  unclassified troubles of, (8) 1446—ab
Wounds, streptococcic infection of, (84) 338
  contused and lacerated, (118) 272
Wounds, modern treatment of, (6) 391
  of abdomen, treatment of penetrating, (45) 1103—ab
  open treatment of, by exposure to sunlight and dry air, (39) 406—ab
  treatment of, on biologic principles, (46) 341—ab
Wrist, traumatic luxation of, (114) 988
Writer's cramp, study of, (23) 854—ab

X

X- and ultra-violet rays in tuberculosis, (11) 733—ab
Xanthoma, case of, (113) 1051
X-ray as therapeutic agent, *26
  dermatitis as influenced by idiosyncrasy, (21) 384—ab
  diagnosis, accuracy in, (18) 1315
  diagnosis of an interesting case, legal status of, (83) 62
  light and high frequency electricity, (50) 491
  light, operating with, (48) 1666
  necrosis, two cases of, (10) 676
  operator, dangers of the, (87) 682, (98) 1051
  technic of Dr. H. Albers-Schonberg, (19) 266
  therapeutic uses of, (80) 800
  therapeutics, report of, (34) 1317—ab
  therapy, (41) 615—ab
X-ray therapy, possibilities of, (97) 1320
  therapy, regulation of duration of exposure and distance from tube in, (21) 975—ab
  treatment, results of, (45) 798—ab
  tube with adjustable focus, *830
  unappreciated uses of, (97) 1051
  work, suggestions in, (150) 63
X-rays and light, cutaneous diseases treated by, (116) 860
  and radioactive solutions to examination of stomach, relation of, (2) 1514—ab
  and rays from salts of radium, comparison between medical uses of, (11) 853—ab
  cases treated by, (10) 130
  diagnostic mistakes with, (48) 685
  diaphragm for, (52) 805
  effects of, on lower animal life and tube best suited for its destruction, (99) 1107—ab
  in pseudo-leukemia, *828
  nature and character of, (53) 336—ab
  to outline the heart, (47) 1111—ab

Y

Yaws; its introduction in Anguilla, (19) 1053
Year's hospital (private) work, brief report of, (105) 1452
Yeast and suppuration, (30) 862
  in therapeutics, (123) 1327
  treatment in gonorrhea in female, (86) 930—ab
Yellow fever and malaria, (47) 1257
  fever, dengue fever, malarial fever and acute yellow atrophy of liver, differential diagnosis between, (59) 491
  fever, does germ of, have its permanent host in Stegomyia fasciata, (120) 682
  fever etiology, new aspects of, *430
  fever, etiology of, (13) 273—ab, (1) 555—ab, (7) 611
  fever mosquito at Louisville, breeding of, (121) 1520
  fever mosquito, mouth parts and salivary glands of, (64) 1451—ab
  fever, prophylaxis of, (74, 78) 1057—ab
  fever, report of French commission, (79) 1057
  fever, tuberculosis and, (101) 203

Z

Zona a seasonal affection, (151) 1396
Zoster, perineal, with notes on cutaneous segmentation postaxial to lower limb, (42) 978—ab

CURRENT MEDICAL LITERATURE

INDEX OF AUTHORS

This Index includes the names of authors of articles which have appeared in this journal, as well as of those listed under Current Medical Literature. This practically includes the names of all who have published articles in the leading journals of the world. The * preceding the page reference indicates that the article appeared in full in The Journal.

has in view must always depend very much on the extent to which his aims are understood by the people and on the support which he receives. It is just here that the active sympathy and assistance of this great organization, paramount in standing and influence over all medical bodies in America, may be of inestimable value.

Another kind of obstruction and opposition, which, I have no doubt, will be fully appreciated by many health officers, comes from the manufacturers and dealers in remedies. I do not wish to lay down the broad principle that in commercialism there is no conscience and no philanthropy, and yet at times I have had reason to think that, while this might not be true as a general proposition, a sufficient number of examples might be cited to prove that it is the rule rather than the exception. Unfortunately, the existence of a disease, and especially of an infectious or contagious disease, may cause a demand for remedies which is of such importance commercially that it is very much to the detriment of the dealers in such remedies to have the disease eradicated. Everybody knows, for example, that if smallpox were completely stamped out, and its importation prevented, there would be very little demand for vaccine; and if diphtheria were eradicated, there would be very little market for diphtheria antitoxin. Now, there are diseases of animals for which similar remedies are being used, and, as it is a case in which human life is not directly involved, commercial interests are the more aggressive to prevent the success of work which means the loss of the market for certain kinds of products in which there are large profits. It is no intention of mine to advocate antagonism to, or warfare against, commercial interests; on the contrary, I fully recognize the value of those great business organizations which have done so much to maintain the standard of drugs and which have been so enterprising in the introduction of new remedies; but when these houses so far forget the interests of the community as to obstruct or hinder the efforts of the sanitarian in the repression of disease, they should be reminded in no uncertain terms that the misfortunes of mankind may not be perpetuated in order that commercial rapacity may be given further and indefinite opportunities. In this effort to uphold the principle that the sanitarian has the right to adopt the best measures at his command for the eradication of disease, whether that disease be one affecting man or animals, and notwithstanding the effect of his success on the sale of remedies, the medical profession and the Bureau of Animal Industry are alike interested.

The investigation of disease by original research according to scientific methods has been a very prominent feature of our work, and we have been able to make some contributions to medical science which are of permanent value. Long before the bureau was established I had been endeavoring with imperfect facilities to prove that immunity against the effects of certain disease-causing bacilli might be produced by injecting into the tissues of animals the toxin developed by those bacilli when grown in cultures. Our success in demonstrating this fact, in 1886, undoubtedly did much to stimulate the study of immunity and to hasten the development of that tremendous aggregation of information on this subject which is now available to the pathologist and to the sanitarian. So, too, the demonstration that the protozoan parasite of Texas fever has a second host, and that this second host is responsible for the infection of the cattle, brought to the attention of scientists a fact of a new order, which led to the discovery that the malarial parasite, the parasite of yellow fever, and various other pathogenic parasites, have their secondary hosts, and the knowledge of this fact has given us our most efficacious methods for the control of these diseases. The bureau has also done much work with tuberculosis and other diseases which is of value to human as well as to animal pathology. We are, therefore, interested with you in maintaining and encouraging scientific research of this character, and in defeating the efforts of those misguided persons who have striven so long and so zealously to restrict, and, if possible, to prohibit, this line of investigations. The American Medical Association has done much already to defeat the efforts to obtain legislation hostile to experimental research in biology and medicine; but those efforts are being continued, and it will require constant watchfulness and aggressive action to preserve that freedom of the investigator which is necessary for prompt and complete success in this difficult field of scientific inquiry.

Now, having tried to give a superficial view of a portion of our work and of some of our difficulties, I will very briefly mention some of the ways in which this Association may assist the bureau in achieving the objects for which it is striving.

1. To secure meat for the consumer which comes from animals free from serious disease. The Bureau of Animal Industry inspects meat in the large establishments which slaughter for the insterstate trade; but there are numerous small abattoirs where animals are killed for local consumption, and where there is little if any inspection. Animals known to be badly diseasesd are often taken to such abattoirs in order that they may be slaughtered without danger of condemnation, and there is a constant stream of diseasesd and unwholesome meat going to the consumer from such sources, which ought to be stopped. The slaughtering in each city should be concentrated in a few places, where inspectors might be constantly present, instead of being done in hundreds of small houses which can only be visited occasionally by an inspector, as is the rule at present. To accomplish this reform a strong influence is needed, and this can be brought to bear legitimately and effectively by the American Medical Association. While this would not be of direct assistance to the bureau, because it is not responsible for meat killed for local consumption, it would, nevertheless, complete the inspection service of the country, prevent the evasion of inspection, and give to our consumers of meat, which means nearly our whole population, a meat supply which is reasonably free from danger.

2. The Association can at all times aid the bureau with its moral support. To do this, it must, of course, be more or less familiar with the work, and must help to educate our people in regard to the importance of maintaining an abundant food supply, and one as free as possible from the contamination of disease. There are now in the United States a number of diseases which must be held in check, or they will make serious inroads on our stock of meat-producing animals, and, moreover, affect the quality of the meat which goes on the market. There are, also, many important problems in pathology to be solved, for which the bureau has special facilities. Some of these problems have almost as direct a bearing on the pathology of man as on that of the lower animals; but even comparative pathology must always be of great interest to this Association. There is, consequently, no organization of men in this country so fitted by its special knowledge and by the similarity of its work to understand our motives, and none which could so intelligently and appropriately commend this service.

3. It is also possible for the Association, if it so desires, to give the bureau its material as well as its moral support. In conducting executive work for the control of diseases, where large business concerns, such as railroad, stockyard and steamship companies, packing houses and shippers of live stock, must be made to conform to inconvenient regulations, there is certain to be opposition, and, although we have the consciousness of right on our side, it is always comforting to know that we have organized support as well as organized opposition. If it is shown, for example, to the legislative and executive departments of our government that the bureau has been and is being conducted in such a manner as to secure your confidence and good will, that would help us to maintain high standards and to press forward with greater energy in the work now in hand.

Finally, there are two important principles in which we are mutually interested, and for the maintenance of which we should co-operate earnestly and unceasingly. The first of these is the freedom of research. How much has been learned by experimental investigations the members of this Association are in a position to know. How much remains to be learned you can judge better than any one else. This one fact must, however, be apparent to all, that infectious diseases, still but imperfectly understood, are causing a large proportion of the mortality, and that more knowledge is required before they can be properly controlled or eradicated. This is equally true with both human and animal diseases. With so much human suffering to be prevented, so many lives to be saved, so much property to be preserved, it is hard to view with calmness the efforts of those who would restrict or abolish, if possible, the class of investigations by which alone we can secure the knowledge for accomplishing these objects. The cause of scientific research, thanks to the efforts of this Association and to the assistance of other scientific bodies, is at present in the ascendant; but restricting legislation is introduced every session into Congress and into the legislatures of some of the states, and it is only by constant vigilance that we can maintain the satisfactory conditions which now exist.

The second principle to which I ask your attention, and the justice of which I think is equally self-evident, is the right of the sanitarian to use the most effective means for the control of disease, without regard to the effect of such measures on the sale of remedies. For example, if a health officer finds that either smallpox or diphtheria is spreading in the district under his jurisdiction, he should be permitted without question to use vaccine or antitoxin to immunize all who may have been exposed, and, if he considers it necessary to his success, to produce these agents under his own supervision and to supply them without charge. The right of the health officer and the right of the bureau to supply immunizing agents for the control of disease is being questioned and opposed through commercial influence, and it seems to me a monstrous proposition either that disease should be maintained in order to preserve the market for certain remedies, or that the power to control disease should be restricted in order that commercial houses may force their tribute from the sufferers. Under ordinary circumstances, where the remedy is furnished of good quality and at a reasonable price, and where the people are able and willing to buy it, it may not be, and probably is not, wise for the community, the municipality or the Government to supply such remedies; but there must be many cases in which these conditions do not prevail, and where the success of the executive measures depends on the prompt and universal use of the immunizing agent throughout the infected district. The bureau has not gone very extensively into the control of disease by this method, but it is experimenting on rather a large scale with one disease, and may find it necessary to handle others in the same manner. By producing the remedy in the bureau laboratory we know its strength, purity, and that it has not deteriorated by long keeping; we also obtain it at first cost. These are important considerations, and their bearing may be such as to determine the success of the failure of a campaign for the suppression of an outbreak of disease. While admitting that the wisdom of adopting this measure must be decided by each executive officer after a consideration of the conditions which prevail in his territory, it appears to me that the right to produce and apply immunizing agents as a sanitary measure should be maintained.

While presenting my views and endeavoring to indicate how this Association may assist the Bureau of Animal Industry, if after mature consideration it is disposed to do so, I wish to add that, whether or not it takes any action of this kind as an association, I shall always be glad in the future as in the past to do anything in my power to further the objects of the Association, and I expect to receive full compensation in the good will of the individual members and in the pleasure of meeting with you and joining in your discussions.

RESEARCH WORK IN THE HYGIENIC LABORATORY OF THE PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

H. D. GEDDINGS.
Assistant Surgeon General,
WASHINGTON, D. C.

From small beginnings, research work in the laboratory of the service has grown to important proportions. It is believed that a short sketch of the growth of the laboratory woulld serve to show better than extended remarks the process of development through which it has passed.

The laboratory was inaugurated as a laboratory of pathology and bacteriology, principally the latter, at the Marine-Hospital of the Port of New York, situated at Stapleton, Staten Island, in 1887. For several years it was in charge of one officer who devoted such time to it only as could be spared from his professional duties in the hospital.

In 1891 the Marine-Hospital Service, having been provided with an office building for its exclusive use, the laboratory was removed from New York to Washington, and from 1891, to March, 1904, occupied one floor of the office building of the service, undergoing meanwhile a steady development.

At an early period after this removal, the advantage was appreciated of constituting in the laboratory a school of instruction for officers whose bent of mind was toward scientific research, and, from time to time, such officers were assigned for duty in the laboratory as assistants, and received a more or less extended course of instruction and training. Such courses were frequently supplanted by details abroad, with the opportunity of visiting and studying at laboratories in Berlin, Paris and Vienna.

Much work has been accomplished during these years bearing directly on the needs of the service. The disinfecting methods of the service as applied in its quarantine and epidemic work were investigated and brought to a scientific basis, both as to agents, the method of their application, and the time necessary for their employment under practical conditions. The result of this work was the elaboration of a system of disinfecting apparatus, which is in use to-day, and which, with the passing of time, have been mechanically improved until they now stand unrivalled.

Departing from the routine use of sulphur dioxid, steam, and solutions of bichlorid of mercury and carbolic acid, it is believed that this laboratory was the first to exploit that extensively employed agent formaldehyd in the combating of infections. The first diphtheria antitoxin manufactured in the United States was the output of the hygienic laboratory of the service. The first authoritative publication on the treatment of diphtheria by antitoxin was issued by the service, and was the direct outcome of personal instruction afforded an officer of the service by Behring and Roux, who separately announced their discovery at the Budapest meeting of the International Medical Congress.

Steadily advancing under the enlightened and fostering care of the surgeon-general, the results of other research were brought from abroad and practically applied in the United States. Plague was studied in the laboratory of the Pasteur Institute by an officer of the Service, and the methods of preparing a curative serum and a prophylactic for the prevention of the spread of the disease were exploited in the laboratory.

An effort was also made, though not crowned with success, to apply the serum of vaccinated calves to the treatment of smallpox. The time afforded was too short, and the quantity of material on hand too limited to do more than break ground in this important direction.

From time to time, bulletins embodying the results of laboratory work have been published. These bulletins now number eighteen, with others in course of preparation and in the hands of the printer. Among other subjects investigated thoroughly and made public in this method may be mentioned bulletins on the "Presence of Tetanus in Commercial Gelatin," "Report on the Prevalence and Geographical Distribution of Hookworm Disease," "A Study of the Impurities of Commercial Vaccine Virus," "An Experimental Investigation of *Trypanosoma lewisi*," "A Statistical Study of the Intestinal Parasites of 500 Patients at the United States Government Hospital for the Insane," "A Study on the Spotted Fever (Tick Fever) of the Rocky Mountains," and others.

It is only proper to say that no subject has been of more importance to the United States and its dependencies beyond the sea than that of hook-worm disease, which, from the bodily weakness and mental depression, which it causes among those infected by it, inflicts an economic loss in certain sections, attained by no other disease.

The "spotted fever" of the Rocky Mountains is a subject of vast economic importance to one of the most fertile and most promising sections of our western country, the disease being attended with great fatality, and recurring every spring, a panic almost has at times prevailed, which threatened to result in the abandonment of this most fruitful section, and the destruction of rapidly increasing agricultural industry.

From time to time, the attention of Congress was invited to the necessity for more adequate quarters for the growing operations of the laboratory, and in March, 1901, this persistence was rewarded by the passage of a section in the bill making appropriations for the sundry civil expenses of the government giving $35,000 for the erection of the necessary buildings, and directing the cession by the Secretary of the Navy of five acres of the Old Naval Observatory site for laboratory purposes.

Some time was spent in the preparation of plans, and, in the meantime, an Act was approved, July 1, 1902, which materially altered the plan and scope of the service, and, at the same time, changing its name from the "Marine-Hospital Service" to "Public Health and Marine-Hospital Service."

In addition to other important features affecting the public health and the relation of the service thereto, the scope of the laboratory was widely extended. An advisory board was constituted, consisting of officers appointed from the medical corps of the Army and Navy, and of a scientist from the Department of Agriculture, and, in addition, five appointees from civil life, not connected with the service of the government, whom it was provided should be persons skilled in laboratory work in relation to the public health. The advisory board consists of Prof. Wm. H. Welch, Prof. Simon Flexner, Prof. Sedgwick, Prof. Victor C. Vaughan, Prof. F. F. Wesbrook, Major Walter D. McCaw, U. S. A., Surgeon J. F. Urie, U. S. N., and Dr. Salmon, U. S. Department of Agriculture.

From a simple laboratory of pathology and bacteriology, the laboratory was increased by this act to one embracing three additional divisions; namely, those of chemistry, of medical zoology and pharmacology.

The building has recently been completed, and the work of these new divisions is now well under way, the division of zoology continuing its investigation into the parasitic disease of man, and the division of pharmacology, in addition to the scientific investigations of the highest import, being engaged in an examination of drugs and medical supplies to determine their potency and pharmacopeial purity.

In addition, an Act also passed July 1, 1902, and effective six months after the date of its passage, provided for the licensing of all establishments engaged in interstate traffic, or in traffic in the District of Columbia in viruses, serums, toxins, antitoxins, and analogous products. This law provides that establishments engaged in the manufacture of these products shall be licensed by the Secretary of the Treasury, and also, preliminary to the issuance of such license, that the establishment shall be inspected by officers detailed for the purpose. It further provides that specimens and samples of these products may be purchased in open market and examined in the laboratory for purity and potency, and that faulty methods of construction, faulty products, false labeling, etc., are punishable by fine and also by suspension or revocation of the license.

This work has been steadily progressing in a quiet and unostentatious way, and the records of the laboratory show a most remarkable improvement in the quality of these products, especially vaccine virus; whereas, before the passage of this law and of the regulations framed thereunder, it was not an uncommon thing to find vaccine which contained hundreds of micro-organisms. In a point of vaccine virus it is not an uncommon thing now to find most of it containing less than 100 per same quantity, with a notable absence of pathogenic and pyogenic organisms.

In accordance with the requests of manufacturers and with the recommendations passed by the American Medical Association and the American Pharmaceutical Association, the preparation of a standard antitoxic unit, for use in the United States, has been inaugurated in the laboratory, and it is hoped that within a few months will be ready for issuance and use.

Aid has been extended to State and local health officers in many directions. The contamination of city and town water supplies by typhoid has been extensively investigated when requested, and recommendations have been made as to their betterment.

Cases of suspected plague occurring in various parts of the country, and arriving at the quarantine stations on our shores, have from time to time been investigated by the laboratory, and have furnished an additional safeguard against the invasion of this disease.

Investigations as to the etiology of yellow fever, and especially as to the relation of the mosquito to the transmission of yellow fever, have formed the subject of investigation in epidemic habitats of the disease by members of the laboratory force and under the auspices of the Yellow Fever Institute of the Service. These investigations have served to amply confirm the original investigations of Reed as to the rôle played by the mosquito in the conveyance of the disease, and are at this time in striking accord with the recently published report of a commission of the Pasteur Institute of Paris, France, on the same subject.

The dissemination of malarial fevers by mosquitoes has also been under investigation, and, in a bulletin now ready for the press, will be found an interesting memoir on the toxicity of filtered malarial blood.

It is difficult within the limits of an address of this sort to state what has been accomplished by the laboratory of the service, so wide and so varied having been its operations, and it is even more difficult to predict limits as to its future usefulness. A progressive spirit actuates the director, Dr. M. J. Rosenau, who is both scientific and enthusiastic, and this enthusiasm he imparts to his assistants, and in a quiet way, without ostentation, almost every important question relating to the public health is the subject of investigation.

The subject of the sanitation of railway coaches and sleeping cars is receiving careful attention, and it is believed that this vital question will be considerably cleared up by investigations which have been continued from time to time over a period of several years.

The service is justly proud of its laboratory, and feels that, while its announcements have been comparatively few, its achievements have been of value and promise an untold amount of good for the future.

French Congress Against Illegal Practice of Medicine.—Dr. Duchesne, the vice-president of the "Union des Syndicats Médicaux" of France, suggested that a congress be organized to discuss subjects connected with the illegal practice of medicine and pharmacy. The Union at once adopted his suggestion, and the organization of the congress is now well under way. Among the subjects to be discussed are the practice of medicine by midwives, masseurs, ministers and priests, and means to remedy it; the rôle of medical associations in combating illegal practice of medicine; medical advertisements in the lay press, their importance and dangers and means of remedy, and the insufficiency of the present measures for repression of illegal practices. M. Baudouin comments editorially in the *Gazette Méd. de Paris* on the proposed congress with some skepticism as to its results. He concedes the value of the influence of congresses in scientific matters, but doubts whether the public powers and established jurisprudence will be influenced by any of the resolutions of such a congress. He remarks: "The legal authorities detest all medical men and are jealous of them. The results desired by such a congress would be better realized by delivering before the legal luminaries a few lectures on the essence of medical science and the art of healing. What we must endeavor to do is to convince the magistracy that medicine is one of the humanities, like jurisprudence itself, and that it varies to infinity with every country and every age, and that in order to learn this science and to make it progress, we must be able to make a living by it and make the rich pay for our apprenticeship and for our experience. This is the very thing which the magistrates are unwilling to admit, and it is for this reason that they do not repress, as they should, the illegal practice of medicine. What would they say, however, if adventurers should come in and deliver legal decisions affecting the magistrates as charlatans now give treatment to men eminent in politics"? "Be this as it may," he adds, "the congress will certainly collect a number of facts worthy of attracting the attention of the public powers."

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

103 Dearborn Avenue . . . . Chicago, Ill.

SATURDAY, JULY 25, 1904.

NATHAN SMITH DAVIS, M.D.

In the death of Dr. Nathan Smith Davis the medical profession has lost a member who always stood for the highest and noblest in ethics, in morals and in right living. Dr. Davis worked long and earnestly for high ideals in medicine, and for the betterment of his profession in every way. He represented before the people the best and purest in that profession, and he always advocated that which he believed to be for the welfare of his confrères and for the good of the people. However, it was as a medical teacher that Dr. Davis was best known, and thousands of men now in practice reverence his name because of the influence he exerted on them during their student days. He was one of the leaders in urging a higher standard of entrance requirements and a more practical method of instruction. Many years before it was adopted he was an advocate of the graded course.

No other man influenced the medical profession as Dr. Davis influenced it. He did not belong to Chicago alone, but to the whole country. Here where he lived his influence was felt to a greater degree possibly than elsewhere, but his was the kind of influence which reached out and permeated the profession of the whole country, if not of the world; and when the true history of medicine in America is written his name will appear more prominently than that of any other man. In his prime—and he was in his prime for more years than most men—he was a power, and usually when he undertook to carry out a project he succeeded. But his success did not come through coercion, through intimidation, or through dishonest methods. Success came because he was earnest in all that he did, because he was governed by absolutely unselfish motives, and because he was always honest and just. These characteristics were recognized even by those who opposed him. So he was believed in and was trusted; hence he was a power. Dr. Davis was a man of whom it might be said "he loved his fellow men," but he loved his profession best. He lived a life of purest simplicity. He never used tobacco, and his opposition to alcohol in any and every form was one of his most noted characteristics; in his death the cause of temperance has lost one of its most courageous exponents.

It is unnecessary to tell about his part in organizing the American Medical Association, and what he did for it in all the long years he was so actively working in it. The records of the Association, as they appear in the annual transactions and in The Journal, are sufficient evidence of the good he did in this regard. The foundation for the present plan of organization was laid by Dr. Davis in the columns of The Journal years ago, and the report he made as chairman of the Committee on Organization in 1887, contained the fundamental principles of the plan on which the profession is to-day organized.

He was a typical representative of the old school family physician; he had the confidence of his patients, was loved, honored and respected by them, and withal was a welcome friend and counselor in every family in which he was known. His was a character to be emulated.

Would that there were more men in our profession like him.

THE INDEX NUMBER.

We take more than usual pleasure in presenting this issue, the index number, for the first volume of the year 1904. The issue of an index to such a large amount of matter is always accomplished with a feeling of satisfaction, for many readers of The Journal have been kind enough to express their high appreciation of this index, and have declared that it is valuable to them and constantly used.

The index to current medical literature is the same valuable feature that it has been in the past. We have given the titles of nearly all articles in the medical publications of the world. A separate list gives the names of the authors of medical articles throughout the world for six months. We thus briefly call attention to this index for the sake of those who are not yet fully familiar with its uses. It is made for use. It will bear study. It will aid in the preparation of articles. It will tell what articles any physician has written. It will indicate a summary of what has been written on any subject. We are open to suggestions as to how future issues may be made still more valuable.

As usual, we make a reprint of the index and incorporate in the reprint the titles that are referred to, and which appeared week by week in The Journal. These titles, with the index to them, present the medical literature of the world for the six months just passed in compact form, for easy and ready reference. The price of this reprint is fifty cents.

THE ROLE OF THE BODY FLUIDS IN PHAGOCYTOSIS.

That the phagocytes play an important rôle in combating certain infections in man, and certain experimental infections in laboratory animals, can hardly be doubted by those who are familiar with the researches of Metchnikoff and his followers. It can be demonstrated that the leucocytes, both in the animal body and in test-tube experiments, take up many cocci and bacilli and apparently destroy them. It has, however, long been a disputed question whether the body fluids take part in this phagocytosis, and, if so, in what way. Some experimenters have believed that these fluids play no part, because they found, for instance, that there may be phagocytosis of the pyogenic cocci, although these organisms multiply rapidly in the cell-free serum and blood plasma of the animals which furnish the phagocytes. On the other hand, there were those who went to the other extreme and held that the phagocytes take up the bacteria only after these have been killed by the body fluids. Gradually these two schools have come closer and closer together, and the recent work of Wright, Windsor and Douglas has done much to settle this long-disputed question of the rôle of the body fluids in phagocytosis.

Wright has shown that the phagocytic power of the white blood corpuscles from patients suffering from chronic furunculosis, acne or sycosis is far below that of the white blood corpuscles of normal individuals. He tested this power of the white corpuscles on staphylococci by inoculating the latter into freshly-drawn defibrinated blood or into blood which had been prevented from clotting by the addition of sodium citrate. A large quantity of staphylococci was introduced into the blood, smears made after a definite period of time, and the number of cocci in each white corpuscle counted. The average number in the white corpuscles of these patients was generally less than half that in the corpuscles from normal persons. Wright now undertook to increase the phagocytic power of the white blood cells in these patients in the hope of thereby effecting a cure of these chronic cases of furunculosis and sycosis of long standing. He accordingly made broth cultures of the staphylococci which he had isolated from the boils, and, after three weeks' incubation, killed the organisms by heating the cultures to 65 C. for twenty minutes. After the addition of 0.5 lysol the patients were inoculated subcutaneously with 0.75 c.c. to 1 c.c. of this vaccine. This inoculation was followed by a local reaction and some constitutional disturbance, both of which were not at all alarming when the first dose did not exceed 0.75 c.c. Six patients were thus treated with three injections, and all were cured of their furuncles. The phagocytic power of the white corpuscles after the treatment was found to be greater than that of the white corpuscles of normal persons, but no destruction of staphylococci by the serum alone could be demonstrated.

Wright and Douglas[1] carried this work farther to determine whether the increased phagocytic power is due to a change in the white corpuscles or in the blood serum. They found that the washed corpuscles derived from the patients who had been treated with the vaccine (immunized), and also the washed corpuscles from a normal person, take up twice as many staphylococci when suspended in the immune patient's serum than when they are suspended in normal human serum. The white corpuscles of a normal person have a strong phagocytic power when they are suspended in the normal plasma or serum, but do not manifest this power except in a very small degree when they are suspended in heated serum or in salt solution. From these observations, Wright and Douglas conclude that the blood fluid plays an important rôle in phagocytosis in that it affects the bacteria in such a way that the phagocytes can more easily ingest them. They believe that this effect is due to a special substance in the serum which they term opsonin (from opsono, I cater for), and that this substance is increased when the patient is treated with the vaccine. In patients suffering from furunculosis and sycosis the opsinic power of the blood is exceptionally low. Opsonin is an unstable substance, as it deteriorates rapidly at room temperature. It is destroyed by Daboia venom, and the experimenters suggest that this may explain why a patient usually gets a generalized infection after poisoning by snake venom. They have shown also that there is no stimulation of the phagocytes by the serum, but the effect of the normal and of the immune serum is exerted directly on the bacteria, although these sera alone are not bactericidal for the organisms used in the experiments.

In using this vaccine certain precautions are necessary. It has been found that the injection of bacterial toxin into a person or an animal is followed by a short period of decreased resistance, which in turn is followed by a period of heightened resistance. If now the system is greatly taxed by a localized infection, the injection of a strong dose of vaccine might be followed by a generalized infection and death. The period of decreased resistance can be reduced to a minimum by starting with small doses of the vaccine, but even then it is necessary to carefully estimate the patient's reserve power of resistance before the treatment is given These experiments are highly suggestive, although they have not yet been confirmed by others.

Medical News.

[As this issue contains the semi-annual index, the amount of space given to news, editorials, and other departments is markedly reduced, and some departments are omitted.]

CALIFORNIA.

Commencements.—The College of Physicians and Surgeons, San Francisco, held its commencement exercises, May 19, and graduated a class of 29.——A class of 24 was graduated, June 16, from the College of Medicine of the University of Southern California, Los Angeles.

Progress of Fight Against Tuberculosis.—During the first year of its existence the Southern California Anti-Tuberculosis League has held two public meetings, and its directors have addressed other public gatherings on the prevention of tuberculosis. It has also published two pamphlets: "Things the Laity Should Know About Consumption" and "Precautionary Suggestions for Those Ill of Consumption," and has provided for the distribution of 80,000 leaflets in Southern California.

---

[1] Proceedings of the Royal Society, 1903-4, vol. lxxii-lxxiii.

State Board Sustained.—The Supreme Court has sustained the constitutionality of the act establishing the State Board of Medical Examiners and making it a misdemeanor, punishable by fine or imprisonment, for any person to engage in the practice of medicine and surgery in this state who has not passed a satisfactory examination before the board and obtained a certificate from it authorizing him to practice his profession. The court holds that it was a proper exercise of the powers of the legislature to demand some standard of efficiency from every practitioner, and the act shows plainly that its main purpose is to admit no one to practice who has not passed an examination in this state or is unable to produce satisfactory proof of having passed one in some other state.

Personal.—Dr. Milbank Johnson, Los Angeles, has been appointed chief surgeon of the San Bernardino Valley Traction System.——Dr. John S. Stephen has been made chief surgeon of the San Francisco Emergency Hospital service, vice Dr. George F. Brackett, resigned.——Dr. Charles V. Cross, San Francisco, has started for Europe.——Dr. Lewis S. Thorpe, Los Angeles, has started on an eight months' tour of Europe.——Dr. Robert B. Williams, Oakland, has been appointed chief surgeon of the North Shore Railroad, with headquarters at Sausalito.——Dr. Thomas C. McCleave, Berkeley, has been appointed physician to the State Institution for the Deaf, Dumb and Blind, succeeding Dr. Oliver D. Hamlin, Oakland.——Dr. Charles W. Bayley, Oakdale, has been committed to the Agnew State Hospital for the Insane.——Dr. Rutherford B. Irones, San Francisco, surgeon of the O. and O. Steamship Company's steamer *Coptic*, has resigned, and will spend a year in travel in Europe.

ILLINOIS.

Hospital Wanted.—Dr. Charles E. Humiston, Austin, has in hand a movement for the establishment of a hospital at some point midway between Austin and Oak Park. The two villages have a population of 50,000, and the nearest hospital is four miles away.

Hospital Notes.—In the new St. Francis Hospital, Kewanee, organizations and individuals have already agreed to furnish 21 out of the 24 private rooms.——Dr. Letitia A. Westgate has decided to sell or close the Sycamore Hospital, which has not been a profitable institution.

Fraudulent Diploma Dealer in Trouble.—Phineas Reisinger of Elba pleaded guilty in the United States District Court, June 9, to a charge of using the mails to defraud, and was sentenced to pay a fine of $50 and to be imprisoned for 30 days. His offense consisted in dealing in fraudulent medical diplomas.

Chicago.

Increased Endowment.—By a lawn fête held in Winnetka last week by the Chicago-Farmington Society, $2,000 was raised to complete the endowment of the Sarah Porter room in the Passavant Memorial Hospital.

Hanish Escapes Law.—"Dr." Ottoman Zar Adusht Hanish, the sun worshipper under indictment for the illegal practice of medicine, was tried and released, the court holding that the prosecution had not made a case.

More Graduates.—At the commencement exercises of Rush Medical College, affiliated with the University of Chicago, June 15, degrees were conferred on a class of 107. Dr. Charles G. Stockton of Buffalo, N. Y., delivered the doctorate address.

Smallpox.—Since January 1 there have been 89 cases discovered and removed to the Isolation Hospital; of these not a single individual had been properly or recently vaccinated. Two patients died, 76 were discharged recovered, and 11 are still under treatment.

Consumption in the Lead.—For the week ended June 11 consumption heads the mortality list with 63; pneumonia takes second place with 53; then come violence with 44, heart diseases with 33, Bright's disease with 25, acute intestinal diseases with 24, and cancer with 21.

KANSAS.

Kansas Medical College, the medical department of Washburn University, Topeka, graduated its first class since the merger, April 21, when degrees were conferred on 25 graduates by President Plass. Dr. William L. Warriner delivered the doctorate address.

State Board Appointments.—Dr. Jonathan B. Carlile, Leon, has been appointed a member of the board, vice Dr. Melvin N. Gardner, Greenleaf, resigned.——Dr. S. Jay Crumbine, Dodge City, has been elected secretary of the board.——Dr. Levi A. Golden, Kensington, has been reappointed a member of the board.

The State Society.—The Kansas Medical Society, at its thirty-eighth annual meeting held in Topeka, May 4, 5 and 6, adopted a new constitution and by-laws, abolished auxiliary congressional districts and elected the following officers: President, Dr. Lawrence Reynolds, Horton; vice-presidents, Drs. Daniel E. Esterly, Topeka, and Edwin T. Shelly, Atchison; corresponding secretary, Dr. George A. Boyd, Baldwin; treasurer, Dr. Lewis H. Munn, Topeka; librarian, Dr. Samuel G. Stewart, Topeka; editor, Dr. George H. Hoxie, Lawrence; delegate to the American Medical Association, Dr. William E. McVey, Topeka, and alternate, Dr. Josiah P. Lewis, Topeka. Wichita was selected as the next place of meeting.

KENTUCKY.

Dr. Leber's Will.—By the will of the late Dr. Frederick C. Leber, Louisville, the entire estate, appraised at more than $50,000, is devised to his widow for life.

Personal.—Dr. Benjamin F. Eager, Hopkinsville, has been made superintendent of Beechhurst Sanitarium, Louisville.——Dr. Benjamin F. Van Meter, Lexington, has been commissioned major and surgeon and assigned to the Second Kentucky Infantry.——Dr. John A. O. Brennan has returned to Louisville after an absence of four years in Europe.

Health Board Changes.—Drs. Orrin L. Reynolds, Edward S. Stuard and Michael Behrman have been elected to the Covington Board of Health.——Dr. Herbert F. Wilson has been elected health officer of Covington, vice Dr. Charles W. White.——Dr. William A. Quinn, Henderson, has been appointed a member of the State Board of Health, vice Dr. Frank O. Young, Lexington, resigned.

State Society Session.—The forty-ninth annual session of the Kentucky State Medical Society was held in Lexington, May 18, 19 and 20. The house of delegates, on May 20, completed the business details of the session, and elected the following officers: President, Dr. Frank H. Clarke, Lexington; vice-presidents, Drs. Leslie L. Robinson, Middlesboro, A. S. Cook, Monticello, and Buckner Littlepage, Clay City; secretary, Dr. James B. Bullitt, Louisville; treasurer, Dr. William B. McClure, Lexington; orator in surgery, Dr. Louis Frank, Louisville; orator in medicine, Dr. Julian T. McClymonds, Lexington; delegates to the American Medical Association, Drs. J. N. McCormack, Bowling Green, and Anselm D. Price, Harrodsburg; councilor for the Eleventh District, Dr. James S. Lock, Barboursville, vice Dr. Benjamin F. Herndon, Barboursville.

LOUISIANA.

Donations to Hospital.—At the monthly meeting of the Eye, Ear, Nose and Throat Hospital, New Orleans, donations amounting to $1,643 were announced.

Society Buys Home.—The Orleans Parish Medical Society has purchased a house which, when remodeled, will be used as the permanent quarters of the society. It will also be used as the headquarters of the state society.

State Society Elects Officers.—At the twenty-fifth annual session of the Louisiana State Medical Society, held at New Orleans, May 10, 11 and 12, the following officers were elected: President, Dr. Charles Chassaignac, New Orleans; vice-presidents, Drs. Oscar Dowling, Shreveport, Leo C. Tarleton, Marksville, and J. F. Buquoi, Colomb; secretary, Dr. Isaac Ivan Lemann, New Orleans; treasurer, Dr. Marion H. McGuire, New Orleans. Councilors: First District, Dr. Paul E. Archinard, New Orleans; Second, Dr. Andrew G. Friedrichs, New Orleans; Third, Dr. Jackson J. Ayo, Bowie; Fourth, Dr. Norwood K. Vance, Shreveport; Fifth, Dr. Sidney L. Williams, Oak Ridge; Sixth, Dr. Charles M. Sitman, Greensburg, and Seventh, Dr. C. A. Gardiner, Sunset, and delegates to the American Medical Association: until 1905, Dr. W. Glendower Owen, White Castle; alternate, Dr. A. Feltus Barrow, St. Francisville; until 1906: Dr. William M. Perkins, New Orleans; alternate, Dr. John B. Elliott, Jr., New Orleans.

PENNSYLVANIA.

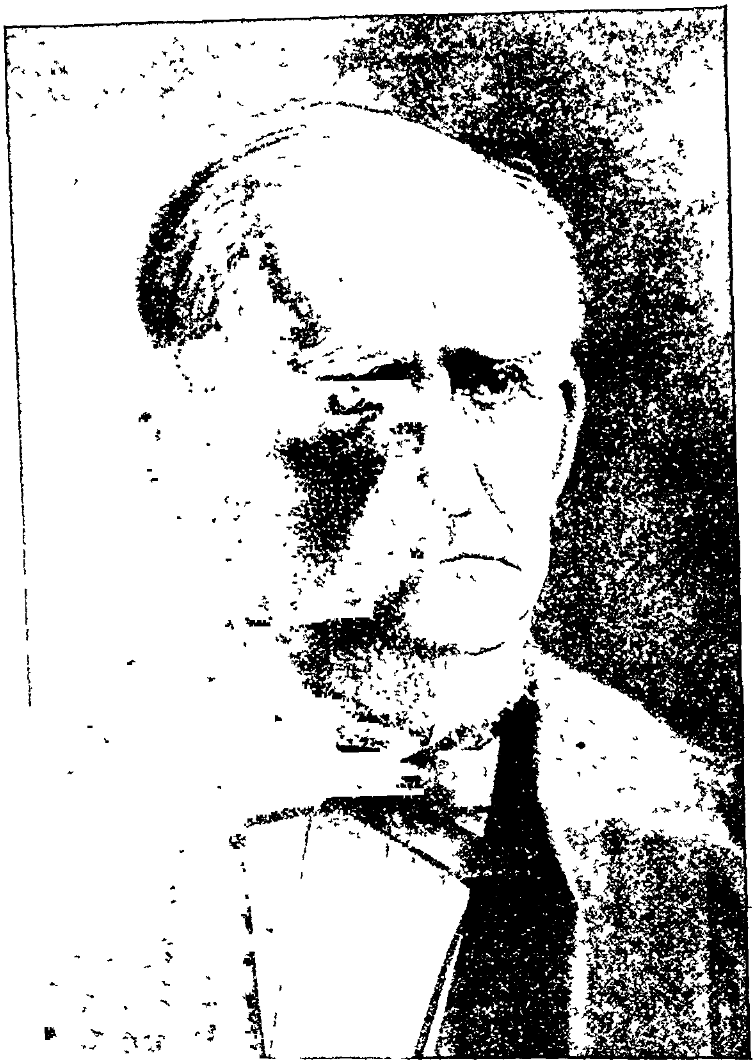
Medical Council Reorganized.—At the meeting of the State Medical Council at Harrisburg, June 11, the following officers were elected: President, Isaac B. Brown, Corry; secretary, Dr. Nathan C. Schaefer, state superintendent of public schools, Lancaster.

Deaths.

NATHAN SMITH DAVIS, M.D.

Dr. N. S. Davis, one of the founders of the American Medical Association, first editor of The Journal, pioneer of scientific medicine, a pillar of strength to the American medical fraternity, died at his home in Chicago, on the morning of June 16, aged 87.

Nathan Smith Davis was born Jan. 9, 1817, on a farm in Greene, N. Y. He lived and worked on the farm until he was 16 years of age, attending district school in the winter, and for six months, Cazenovia Seminary. At the age of 17 he began the study of medicine under Dr. Daniel Clark of Smithville Flats, N. Y., attended three courses of lectures at the College of Physicians and Surgeons of the Western District of New York, Fairfield, and was graduated from that institution, Jan 31, 1837. He chose as the subject of his thesis "Animal Temperature," and maintained that body heat is evolved through metabolic processes.



NATHAN SMITH DAVIS

From the latest photograph, taken about two months before his death

He first practiced in Vienna, Oneida County, N. Y., but after a few months moved to Binghamton, and soon after settled in New York City. It happened that this was the year of the terrible visitation of cholera in New York, when many physicians were afraid to remain, but Dr. Davis went boldly among the sick, receiving no harm himself and acquiring great local reputation for faithfulness and earnestness.

In 1841 he was awarded the prize offered by the Medical Society of the State of New York for the best "Analysis of the Discoveries Concerning the Physiology of the Nervous System." About seven years later the State Agricultural Society of New York awarded him a prize for a "Text-Book on Agricultural Chemistry."

He became a member of the Broome County Medical Society, and was one of its censors in 1838. In 1841, 1842 and 1843 he was secretary and librarian of the society, and in 1843 delegate from Broome County to the Medical Society of the State of New York.

In 1845 it was Dr. Davis' report as chairman of the Committee on Correspondence relative to Medical Education and Examination which, after adoption by the Medical Society of the State of New York, led to the organization of the American Medical Association. The resolutions adopted at that time are as follows:

Whereas, It is believed that a national convention would be conducive to the elevation of the standard of medical education in the United States, and

Whereas, There is no mode of accomplishing so desirable an object without concert of action on the part of the medical societies, colleges and institutions of all the states, therefore

Resolved, That the New York State Medical Society earnestly recommends a national convention of delegates from medical societies and colleges of the whole union, to convene in the City of New York, on the first Tuesday in May, in the year 1846, for the purpose of adopting some concerted action on the subject, set forth in the foregoing preamble.

Almost from the beginning of his career, Dr. Davis was identified with medical education, and was one of the first to advocate and to continue his advocacy of a higher curriculum and more rigid requirements. While he was living in Binghamton, he obtained a cadaver and demonstrated anatomy to medical students. His first work as a teacher was lecturer and demonstrator of anatomy in the College of Physicians and Surgeons in the city of New York in 1848. A year later he moved to Chicago and accepted the chair of physiology and pathology in Rush Medical College, and a year later in addition, assumed the duties of the chair of practice of medicine, and remained connected with the institution for ten years.

Soon after he became connected with this college, he appreciated the necessity of a better system of medical education, as at that time there was no classification of students and no adjustable curriculum. He began to agitate for reform, but was opposed. He continued his war for progress, until he was satisfied that he could not gain his point. He therefore withdrew, and with a few other progressive young men of that day, of whom Dr. John H. Hollister is now the only survivor, founded the Chicago Medical College, of which he was for more than forty years the dean and professor of principles and practice of medicine.

When Dr. Davis arrived in Chicago, there was no organization of physicians, and he was one of the prime movers in the organization of the Chicago Medical Society and of the Illinois State Medical Society. For twelve years he was secretary of the Chicago Medical Society, and in 1855 served as its president.

Soon after his arrival in Chicago, there was an epidemic of malarial fever, and he found on analyzing the drinking water that it was polluted by sewage. He straightway began agitation for a system of drainage, and to this end delivered a number of lectures, exacting a fee for admittance, the proceeds of which went to the founding of beds for the sick. As a result of these lectures, Chicago entered on a system of sewerage construction, and the fees received from the lectures went toward the foundation of what is now Mercy Hospital.

His editorial work began while he was residing in New York City, where he was editor of the *Annalist*. In 1855 he took editorial charge of the *Chicago Medical Journal*, and five years later the *Chicago Medical Examiner*, remaining in editorial conduct of these two journals separate and combined for twenty years. It was chiefly through his efforts that The Journal of the American Medical Association was established in 1883, and he was its first editor, continuing in that position for six years, when he resigned.

He was a member of the International Medical Congress in 1876, and at that time read a notable paper on "American Medical Institutions." In 1887 he was secretary-general and later president of the Ninth International Medical Congress which met in Washington. During his arduous work of collaboration of the plan for this congress, he was stricken with cerebral hemorrhage, but had sufficiently recovered in three weeks to resume his official and private professional duties.

He was one of the founders and trustees of Northwestern University of the Chicago Academy of Sciences, the Chicago Historical Society, Illinois State Microscopical Society, Union College of Law, of which he was professor of medical jurisprudence, and the Washingtonian Home for the Reformation of Inebriates; an honorary member of the British Medical Association, and many other scientific societies in this country and abroad, a charter member of the American Medical Association, American Medical Temperance Association, Illinois State Medical Society, and the Chicago Medical Society.

He was vice-president of the American Medical Association in 1854, president in 1864 and 1865, and trustee from 1882 to 1884, editor from 1883 to 1888, and orator in medicine in 1890.

Dr. Davis was a voluminous writer. Among his chief contributions to the medical literature are his "Principles and Practice of Medicine," "Medical Education and Reform," "Verdict of Science Concerning the Effects of Alcohol on Man," and "Clinical Lectures," in addition to the essays already noted.

In 1876 he was first attacked by prostatic disease, from which he suffered until his death. About ten years ago the presence of interstitial nephritis was first noted. Notwithstanding the discomfort and distress occasioned by his physical condition, Dr. Davis regularly attended to his professional duties, walking to his office every morning and from his office every afternoon until a short time before his death. On June 5 he was taken ill, complaining of distress in the chest, which gave rise to a suspicion of angina pectoris, and Cheyne-Stokes respiration quickly developed with nausea, vomiting, suppression of urine and other signs of uremic poisoning. Cheyne-Stokes respiration continued with remissions until his death. Difficulty in breathing and pain around the heart were also more or less continuous. Up to within one hour of his death he talked clearly and well. He died June 16 at 8 a. m., quietly and without pain.

His funeral was held June 18 from his late residence, 291 Huron Street. His older grandsons—Dr. J. D. Kales, and Messrs. W. R. Kales, A. M. Kales, F. H. Kales, F. H. Davis and Nathan S. Davis III—were the active pallbearers, and Drs. J. H. Hollister, E. C. Dudley, J. E. Owens, W. E. Quine, Frank Billings, F. S. Johnson, George H. Simmons, and Messrs. William Deering, F. P. Crandon and James H. Hobbs acted as honorary pallbearers. The interment was at Rose Hill Cemetery.

At a special meeting of the Chicago Medical Society, June 17, a committee of seven was appointed to arrange for a memorial meeting to be held in October.

James Henry Dunn, M.D., one of the most eminent surgeons of the northwest, was found dead in his room at the Southern Hotel, St. Louis, June 16, probably from heart disease, aged 51. He was born in Fort Wayne, Ind., May 29, 1853, had his preliminary education in Winona, Minn., read medicine with Dr. J. B. McGaughey, Winona, in 1875, attended one course of lectures at Rush Medical College, Chicago, and two courses at the University of the City of New York, receiving his degree at that institution in 1878. He opened an office in Shakopee, Minn, in 1880, and was appointed deputy of the State Board of Health during the smallpox epidemic of 1882. From 1883 to 1885 he studied in Heidelberg and Vienna, paying special attention to surgery and genito-urinary diseases. On his return to the United States he established himself in practice in Minneapolis. From 1886 to 1888 he was city physician of Minneapolis. He was professor of skin and venereal diseases in the Minnesota Hospital Medical College from 1885 to 1889; professor of genito-urinary diseases in the College of Medicine and Surgery of the University of Minnesota from 1889 to 1894, and since that time has been successively adjunct professor of clinical surgery, professor of clinical surgery and professor of surgery in the University of Minnesota. He was for 18 years surgeon to St. Mary's Hospital, for 12 years surgeon to the Asbury Methodist Hospital, and for 11 years surgeon to the City Hospital, Minneapolis. He was a member of the American Medical Association, the Western Surgical and Gynecological Association, member and president in 1888 of the Minnesota State Medical Society, a member of the Minnesota Academy of Medicine, Hennepin County Medical Society and Minnesota Valley Medical Society. He was a fellow of the American Surgical Association, and had read a paper before the association on the day of his death.

Marriages.

Eldridge E. Wolffe, M.D., to Miss Aimee Hooper, both of Cambridge, Md., June 7.

Ellsworth Eliot, Jr., M.D., to Miss Lucy C. Byrd, both of New York City, June 14.

Bernard Hurt Stamberg, M.D., St. Louis, to Miss Marion Frances Kriete, at Dansville, Va., June 6.

Carl E. Jumper, M.D., Terre Haute, Ind., to Miss Ellen J. Pollard, in King George County, Va., June 5.

Hugh McGavin, M.D., Plum Coulee, Manitoba, to Miss Ada Jane Jones, at Kildonan, Manitoba, June 1.

William Hupp Sands, M.D., Fairmont, W. Va., to Miss Gertrude Christian Du Bois, at Millersville, Md., June 4.

George W. Crabtree, M,.D. first lieutenant and assistant surgeon, U. S. Army, Governor's Island, N. Y., to Miss Ines May Kelly of Boston, June 3.

Correspondence.

The Prevention of Syphilis.

Chicago, May 24, 1904.

To the Editor:—The crusade for popular education against tuberculosis suggests the reminder that another endemic infection, syphilis, could be eradicated far more quickly, surely and easily than can tuberculosis. While the proportion of our adult population already syphilized is indeterminate—being variously estimated at 5 to 15 per cent.—yet the rapid increase of this proportion is universally admitted; and we are just beginning to appreciate the extent and variety of the ravages of remote syphilis in the internal organs.

This disease can be restricted, not by licensing prostitutes—already proven a failure in Europe—nor by educating youth to chastity, for this laudable effort is proved impotent against the polygamous instinct of the mammalian male; but by making the acquisition of syphilis by the male practically impossible through circumcision.

It is notorious that Jews furnish relatively few cases of syphilis; that this immunity is not due to their superior continence is shown by their frequent acquisition of gonorrhea; that it is due to the hardening of the puerile covering through early circumcision, and consequent freedom from abrasions during intercourse, is obvious. This rarity of syphilis is observed among all circumcised races—whether Mohammedans, Buddhists or (Abyssinian) Christians. The early Egyptian practice of circumcision just before puberty is one of several facts which suggest that the general adoption of circumcision by the early Semitic races was for protection against syphilis.

The evils of remote syphilis can be reduced by impressing on the syphilized two injunctions: 1, To take antisyphilitic remedies for two months in each year after the termination of active treatment; and 2, to inform any physician who may at any time be consulted for relief from a chronic ailment, of the early syphilitic infection. WM. T. BELFIELD.

Co-ordination in Government Medical Service.

To the Editor:—It would be an excellent thing could the Committee on Legislation of the American Medical Association study the medical services of the United States as to the number of men employed, the character of the work done, results attained, together with the costs in money outlay. These medical men will be found, I think, as follows:

Marine-Hospital Service, Navy Medical Department, Army Medical Department, doing biologic work in the Department of Agriculture (see the work of Stiles on human parasitology, Atwater's food and calorimetric studies on man), in the Department of the Interior as medical examiners in pension cases; and it is possible that there are yet others in the Census Bureau as statisticians in medical statistics. Then, with a summary of this work, its costs and efficiency: the faults and failures of the present system.

This study will show that there are employed in various capacities by the general government some 2,000 or 2,500 medical men, serving under at least four and perhaps more secretaries of the presidential official family. The force is scattered and no one department can legally call on another for medical assistance; the hospitals, libraries, laboratories and schools are duplicated and triplicated; they are without a common medical head, but each subdivision has its own head, a layman without knowledge of medicine, through whom the department reports to the President, the executive head of the nation. What opportunity has the President under such conditions to obtain a comprehensive working knowledge; to enable him to co-ordinate the medical information he has received with the reports of other conditions which he receives from his other secretaries from the same point, when receiving such a report from a man who is unable to explain to him the points which are not clear?

What would have happened to the United States when the bubonic plague made its appearance in San Francisco, had it not been for J. J. Kinyoun's work? This dread disease would have spread over the entire United States, and would have cost the United States many times the money paid out for the entire medical service from the foundation of the government to the present; as it was, the interstate law enabled the P. H. & M.-H. Service to force, through the operation of interstate quarantine, a partial compliance with sanitary obligations which resulted in stamping out the disease. The business men of California almost succeeded in allowing their greed for money to infect the entire country with this disease.

Having had these studies and compilations made, calculate, on current prices, the costs, etc., of a new Department of Public Health, with a secretary of public health a medical man, to be chosen by the President from the public at large, who is engaged in the active practice of his profession, and confirmed by the senate. Consolidate all medical service to the United States under this secretary of public health, consolidate the hospitals, libraries, laboratories, and schools from their present semi-chaotic state, make up your costs and comparisons in dollars, and the saving in actual money will be very large.

Then compare the efficiency in applying laws relating to food supplies, medicines, water supplies, in controlling threatened epidemics, the ability to meet sudden calls on the medical service of the United States, like that which existed in 1898, when 250,000 men were called for the Army and many for the Navy. Under the conditions mentioned, there would have been a large number of trained men who could have at once gone to the front, while their civilian brothers would have replaced them in post hospitals, the marine hospitals, laboratories, etc., where they would have worked acceptably to themselves and the government, the rush being slight, and the work almost that to which they are accustomed in civil life, while these men, trained in public health technic, understanding the necessary red-tape of the department, took the rough end of the work at the front, meanwhile training their civilian brother into the red-tape (administration work) of the public health official, as might fall in either the Army, Navy or Marine-Hospital Service.

These medical men to be in no way responsible for their work to the military or naval commander, and having in no way any control over either soldier or sailor, when not in hospital, but to be the representative of, and reporter to, the President on all sanitary and medical questions in the army or navy, and as the executive in all international, interstate and interisle and quarantine matters, and as such the representative of the executive in all medical matters, reporting direct all insanitary conditions which may threaten the country or the country's forces, to the executive at the center; who can then balance the report with other reports and issue such orders as he may see fit; with sanitary conditions considered as are other conditions, the Secretary of Public Health explaining to the President what the conditions reported threatened to the command or to the country at large.

To leave medical men in their present condition of subordination to men who know nothing of these matters is to result in medical men reporting conditions just far enough to enable them when bad results come, to point to the report and say: "I reported the facts and pointed out the dangers"; for the responsible man to say: "I am no *doctor*, I did not understand the force of the report; I exercised my best judgment," and nobody is responsible. Meanwhile men die, the costs go mounting up, an epidemic is well under way, and nobody is responsible; the medical man, because he advised the executive, because he did the best he knew how, and all join hands to call the failure to fix the responsibility a visitation of God, and to say that it was impossible to avoid.

The local boards of health attain the results aimed at, whereas failure to obtain them is the universal history of all armies in war and peace.

With this should go also a public health medical school, to which young graduate medical men and graduate nurses should be sent to receive a postgraduate course, of two or three years, to train them in the laws and customs of this highly specialized service, which has been so much neglected by the profession at large, namely, caretaking of the public health.

To sum up then, it would appear that an excellent formation for this purpose would be: A secretary of public health, a cabinet officer; A public health medical service, to be composed of: Medical officers, graded, and nurses, clerks, mechanics, and laborers, all graded and classified; and lastly a public health medical school, in which to train all medical men and nurses in this service, and to which they should be returned for study from time to time, and from which entry into the Public Health and Marine-Hospital Service is to be made, after the original formation of the service.

It has been suggested that the same end might be attained by transferring the three present departments to a public health department and keeping the present men at their present work, and let the change come little by little, all new appointments to be made in the public health service, and thus save heart burning.

VOMITING IN PREGNANCY.

Nebraska, June 7, 1904.

To the Editor:—Can you give me the name of some good remedy for vomiting, especially the vomiting of pregnancy? I have had several cases during the last year and have failed miserably of success. I have tried the most common remedies without effect: nux vom., cerium oxalate, pepsin, ingluvin, bromids, bismuth, ipecacuanha, mercury, opium, lime water, etc. M. M.

Answer.—Vomiting of pregnancy has been ascribed to many causes, and many remedies and methods of treatment have been recommended to combat it. Recently a number of obstetricians have been inclined to ascribe it to an intoxication of the maternal organism by fetal or placental products. Whatever may be the underlying cause there can be no doubt that sources of peripheral irritation, like a dilated and inflamed stomach, a constipated bowel, tight corsets, a retroverted and retroflexed uterus, etc., are very important accessory factors. In accordance with this view of the etiology the management should consist in removing carefully and as thoroughly as possible all the complicating factors. The diet should be carefully regulated, if necessary the stomach washed out, the bowels well emptied, a displaced uterus replaced and all constricting bands or corsets removed. If the vomiting is severe or continuous the patient should keep in a horizontal position, and in bad cases she should receive rectal injections of alcohol and salt solution. In all cases a hot drink in the morning some time before rising is desirable. Drugs play a very secondary rôle in the treatment. Laxatives are sometimes necessary, as indicated above. Bicarbonate of soda or bismuth, etc., may sometimes have a temporary value. There is, however, no specific or "sure cure." That physician will have the best success in managing these cases who searches out the important etiologic factors and removes them. The nervous element is especially important in these cases, and the physician who has a confident and masterly presence and carriage, one who believes in himself and his ultimate success, has a great advantage.

THYROID ENLARGEMENT.

Seattle, Wash., May 26, 1904.

To the Editor:—Does the following patient require treatment and should she remain single: Female, 24 years old, has had a small enlargement of the thyroid gland for the past twelve years. Sometimes it enlarges slightly, but soon recedes. General health is good, not nervous nor hysterical. No protrusion of the eyes and pulse about 90. If she requires treatment, what would you suggest? One year ago she moved from the middle states.

A. J. H.

Answer.—The careful investigations of Lange of Koenigsberg, published in 1899, have confirmed the idea long held that there is generally an enlargement of the thyroid gland during pregnancy. Lange found that this enlargement appears during the fifth or sixth month of pregnancy and disappears seven to fourteen days after labor. He also has found an interesting connection between the hypertrophy of the thyroid and the action of the kidney. In 25 cases where there was no enlargement of the thyroid, out of 133 examinations, he found albumin in the urine 18 times. In none of the cases of thyroid hypertrophy was there albumin or evidence of the existence of kidney disease characteristic of pregnancy. In cases of kidney disease with albumin the administration of iodo-thyroidin improved the urinary secretion and decreased the amount of albumin. In his experiments on cats that also have thyroid swelling during pregnancy he showed that if more than 4/5 of the thyroid was removed from pregnant animals tetany occurred that was favorably influenced by the administration of thyroidin or iodo-thyroidin. A greater amount of thyroid tissue must be left in a pregnant animal than in one nonpregnant to preserve its health. If a large amount, but less than 4/5 of the thyroid gland be removed, the kidney undergoes parenchymatous degeneration and the animal falls into convulsions or a state of coma. Lange concludes from these observations and experiments that there is produced during pregnancy, probably by placental metabolism, a substance that stimulates the thyroid to increased growth and activity resulting in an increased thyroid secretion containing antitoxic properties. If this fails the kidneys have extra work to do and are apt to suffer as a result. If this theory be true, it follows that thyroid disease or insufficiency may be of serious consequences in pregnancy. It is not probable, however, that a case of slight enlargement like that reported in the inquiry would have any serious importance. There seems to be no insufficiency of gland secretion at present. Probably some physiologic hypertrophy would take place during pregnancy. Whether this would be so great as to cause a mechanical obstruction to respiration can not be foretold, but in case such a symptom should arise it could be controlled by the use of thyroidin. Hence we should answer that there is no ground for forbidding marriage in this case, nor should we anticipate trouble during pregnancy. It would be the part of prudence in case of a supervening pregnancy to keep the patient under observation, and if necessary administer iodo-thyroidin in doses of 10 to 25 grains a day. Otherwise no medication would be required.

DOCTOR PAYS FUNERAL EXPENSES.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Sodium Bicarbonate in Gastric Troubles.

Huchard, in an abstract in *Jour. Amer. Med. Sciences,* states that sodium bicarbonate is indicated in small doses (3 to 5 grains, .20-.30), taken one-half hour before eating, in the treatment of anorexia, as it increases the secretion and excites the contractility of the stomach. He prefers it to the bitters. In hyperchlorhydria it is indicated in large doses at the end of the period of digestion, two or three hours after a meal, when the gastralgia is likely to occur. In this latter condition he recommends it in 4 or 5 dram (15.-20.) doses daily for several weeks, and states that he has seen no evil effects from its use in such doses; on the contrary, oxidation and metabolism are favored and an increase in body weight. The gastric crises of tabes, when accompanied by hyperchlorhydria, respond to the sodium bicarbonate given in 5-dram doses (20.) per day. He thinks it is the remedy par excellence in diabetes, in the prevention of coma, which condition is characterized by true acidemia. The dosage in this disease should be at least 2.5 drams (10.) daily, and where coma exists as large a quantity as three ounces may be given. In dermatoses of arthritic origin, alkaline medication is indicated, giving the sodium bicarbonate in 3 or 4-dram doses (12.-15.) per day. In biliary lithiasis and hepatic colic one of the surest methods of cure, according to the author, is alkaline medication employed in large doses.

In gastric dilatation accompanied by hyperchlorhydria, Sowpault, in *Jour. de Méd. de Paris,* recommends the following:

℞.	Sodii bicarb.		
	Cretæ prep.		
	Bismuthi subnit., āā	gr. viiss	50
	Magnesiæ (calcined)	gr. v	30

M. Ft. chart. No. i. Sig.: One such powder every three hours.

And for the constipation:

℞.	Sodii phos.	gr. lxxv	5
	Sodii bicarb.	ʒi	4
	Sodii sulph.	gr. xlv	3

M. Ft. chart. No. i. Sig.: One such powder dissolved in a quart of water, and take a glassful each morning on rising.

Camphor Hypodermically.

J. I. Johnston, in *Med.,* states that camphor is a valuable cardiac stimulant, even as good or better than strychnia. In addition to its stimulating properties it is a cerebral sedative. He recommends it especially in infectious conditions where there is mild delirium associated with cardiac failure. When administered hypodermically it should be dissolved in olive oil in the proportions of 2 grains (.12) of camphor to 10 minims (.65) of the oil, the dose of camphor being from two to six (.12-40) grains. He states that he frequently gives a daily dose of 24 to 36 grains (1.50-2.40) for several days. There will be no danger of abscess with proper precautions and aseptic olive oil.

Calcium Chlorid in Nephritis.

G. Gross, in *Klin. Ther. Wochenschr.*, recommends calcium chlorid administered per rectum in the treatment of hemorrhagic nephritic, also in cases of inoperable uterine carcinoma, with profuse hemorrhages. After giving a cleansing enema the salt may be given as follows:

℞. Calcii chloridi ....ʒiiss 10|
Aq. destil.............................℥viss 200|

M. Sig.: The entire amount administered per rectum. The same may be given by the mouth as follows:

℞. Calcii chloridi ....ʒi 4|
Syr. menth. pip ....℥i 30|
Aquæ destil ....℥iii 90|

M. Sig.: One tablespoonful every two hours.

Medicolegal.

Woman on Whom Abortion Is Performed Deemed But Victim.—The Supreme Court of Tennessee says, in Smartt vs. State, that the Tennessee statute on the subject of abortion does not fix any crime on the woman who is the subject of an abortion, or attempt at abortion. It is directed against those who perform the abortion, or attempt to perform it, on her. She is the victim, and is neither principal nor accomplice, under the law, where the act is performed, or attempted to be performed, on her by another. Moreover, the weight of authority elsewhere is to the same effect. And it is held that, not being an accomplice, she does not need corroboration in her testimony. But her moral implication is a proper question for the consideration of the jury in weighing her testimony.

Assault to Commit Rape After Administering Chloroform.—The Supreme Court of Colorado says, in Harlan vs. People, where it affirms a conviction of a dentist of an assault to commit rape, that it is uniformly held that one who carnally knows a woman while she is in a state of stupefaction is guilty of rape. And there can be no doubt that, if the accused in this case had at the time he administered chloroform no unlawful purpose, yet, if he afterward formed the design and purpose to have sexual intercourse with the woman while she was under the influence of chloroform, and while she was in such a condition from the effects of the chloroform that she was unable to remonstrate or resist, and that while harboring such intention he undertook to have sexual intercourse with her, he was guilty of an assault with intent to commit rape, although the assault was one without violence, and although he desisted before accomplishing his purpose.

Admissibility of Hospital Records in Injury Case.—The Supreme Judicial Court of Massachusetts says that in the case of the books which were offered as records of certain hospitals, in the personal injury case of Cashin vs. the New York, New Haven & Hartford Railroad Company, that it was not contended that, as to either institution, the records were kept under any requirement of law. They were, therefore, not public records, and were not admissible, unless supported by the testimony of the one who made them, if that person were still alive and capable of being produced to testify. In the case of Townsend vs. Pepperell, 99 Mass. 40, the record was admitted evidently on the doctrine that, it being more than 30 years old, there was no need to show the death of the person who made it. But in the present case the court may well have found on the evidence as to each hospital, both that the records were imperfect, and that there was no reason to suppose that the writers could not be produced. The records on such a finding were properly excluded.

Moral Insanity as a Criminal Defense Not Recognized.—The Supreme Court of Nebraska says, in Bothwell vs. State, where the former was charged with the crime of rape on his daughter and the defense was insanity, that the generally accepted test of responsibility for crime is the capacity to understand the nature of the act alleged to be criminal, and the ability to distinguish between right and wrong with respect to such act. Moral insanity as a criminal defense is not recognized in Nebraska. One who knows abstractly what is right and what is wrong must, at his peril, choose the right and shun the wrong. He can not yield to a vicious impulse and allege mere weakness of will as an excuse. The Supreme Court says further, in the case, that, while the brief of counsel for the accused was interesting in its discussion of the varied forms, manifestations, and stages of mental diseases, and pleaded for an idealistic state in the treatment of those who may not be possessed of the strong, healthy, and vigorous minds possessed by the average of humanity, yet, nevertheless, in this practical age, and as society is at present constituted, the court is of the opinion greater evils would flow from a departure than in continuing to travel along the well-beaten paths which guide and determine legal responsibility for violations of the law.

1 *Tuberculous Pericarditis, with Report of Case. Charles G. Stockton.

1. **Tuberculous Pericarditis.**—Stockton remarks that tuberculosis has been naturally accepted as a cause of pericarditis. Osler has urged its frequency, though Beverley Robinson and others consider it comparatively rare. He reports cases at length, notes the points of interest, and considers the following conclusions warrantable:

1. Tuberculous pericarditis is not a rare affection.
2. The diagnosis is usually not made except in cases with simultaneously active tuberculous processes in other parts.
3. The concurrence of pleurisy with blood-stained effusion may be regarded as suggestive.
4. The pericarditis may be of a chronic obliterative type, or there may be massive effusion, generally sanguinolent, but rarely purulent.
5. It may be acute, continuing for but a few days, or chronic, existing for many months.
6. It may be a part of a multiple serositis, and the proportion of cases in which at least one or more of the pleural cavities are involved is remarkable.
7. The disease is to be regarded as a secondary affection, although from a clinical point of view some cases may be looked on as primary.
8. The point of origin of the infection is often found in the bronchial and mediastinal lymph nodes, although these may be quite exempt from the disease. The infection may be direct from continuity of tuberculous tissue, or by transmission through lymph vessels or through the circulation.
9. The heart may be greatly enlarged, or normal in size, or even somewhat small.
10. Some observers believe that occasionally the process subsides and that comparative cure results.

7 *Constitutional Low Arterial Tension. Louis Faugeres Bishop.

3. **The X-Rays.**—Branth reports and illustrates cases of the uses of the x-rays in superficial malignant growths, diagnosis, etc., and calls attention to its employment in epilepsy, report-

ing his experience. The theory of its action was that the *x*-ray stimulated the protoplasm into greater vital activity, thus overcoming the instability of the abnormal metabolism which is the cause of the disease. Three treatments a week are given, beginning with five-minute exposures, at fifteen inch distance, and increasing by degrees to ten-minute exposures at ten-inch distance, a different part of the skull being exposed at each sitting. A hard vacuum tube with a 5 or 10 spark gap in the circuit was used. One of the drawbacks of the treatment is the possible loss of hair, but Branth prophesies that this will be put temporary, and that the hair will return in stronger growth than before. He remarks that the patients gain in weight under this treatment, that the *grand* and *petit mal* seizures become lighter and of shorter duration, less frequent and followed by less prostration. *X*-rays are not used often enough in diagnosis. His preference is the static machine, because it gives a steadier *x*-ray light. Most of his work has been done with the Gundlach tubes, though the new regulating Müller tube seems to possess some points of superiority. *X*-ray work requires the skill of a photographer, as well as medical acquirements.

4. **Fracture of the Radius.**—Kenerson concludes his article, describing a special method for reducing fracture in a comparatively painless way, often without anesthesia. He places the patient in a high office operating chair in the upright sitting position, with the hand extended in front, the plane of the hand being perpendicular to the floor. He uses a skein of coarse woolen yarn wrapped over the wrist, with the loop knot fixed at a point on the upper side of the wrist, as the hand is extended as directed. The free end of the skein of yarn is fixed to a post or door jam by means of a staple at a height corresponding to the patient's shoulder. Then grasp the patient's forearm with the hand opposite to that which is injured in the patient, making slow but steadily increasing counter-traction on the patient's arm until the arm is fully extended and the wrist is tired out somewhat; then there will appear a lessening of the deformity, and, usually, a complete reduction of the fracture at the wrist without touching the point of fracture. The lessening of the deformity will not remain unless you "jack back" the fragments of the broken radius, when perfect and permanent reposition can be secured. The hand should then be held in a forced extended position until the muscles have relaxed, and then the strain can gradually be lessened and the fragments will stay in place. The advantages of this method are summed up by Kenerson as follows:

> 1. Once carefully arranged, with the skein of yarn adjusted as directed and made fast to the wall or some other convenient standard, and gentle traction having been started, the patient can not get away from the treatment, and usually if the traction is intelligently applied, will not try to get away. But all manipulations and adjustments of the yarn and the steadily increased traction must be proceeded with methodically and confidently.
> 2. Even with a patient of muscular build, and a surgeon of slight muscular power, sufficient traction can be applied so that the reduction is easy and perfect and complete.
> 3. It is applicable to practically every fracture of the lower end of the radius ("Colles") that you meet, the interarticular being represented only by a very small percentage.
> 4. It is seldom necessary to give any anesthetic.
> 5. All the details can be attended to by the surgeon if he is alone; but, of course, it is always convenient to have some one at least to assist in handing the splints that have been prepared before the "setting" of the bone.
> 6. The manipulation with the skein of yarn meets every anatomical requirement—namely, that the extension be applied so as to pull the hand toward the ulnar aspect of the arm, that the ulna be pressed at its tip toward the median line of the wrist to keep it in proper place so that it will not slump after the setting, and at the same time will leave the hand and the radial side of the wrist free for inspection and manipulation. In this case, *or* in any other case of reduction, after the reduction of the fracture, it is wise to allow the hand to lie on a pillow for a few moments after the fracture is in place and without any support, and if this is done and the fragments when left to themselves do not again become displaced, you may be sure that they will stay in place after the splints have been applied. It is the fractures that have been partially replaced and then held while some retaining splint has been applied that become displaced and heal with faulty union.

It is well to see that you have succeeded in getting the fragments fully back and opposed to each other so that they will remain in place. After they have stayed in place for a few minutes and the temporary splints have been secured with adhesive plaster, you may be sure that the deformity will be slight, and that the radius, at least, will be straight. A temporary splint must be applied until the swelling subsides, and some device must be obtained that will furnish constant pressure on the lower end of the ulna, which is so seldom broken, and that will not, at the same time, displace the radius. He claims the method practicable for Cole's fracture and will insure good results, even in the hands of those who treat but a limited number of cases.

5. **Tuberculosis.**—Flick points out the needs of municipal action and the methods that should be employed in combating tuberculosis.

7. **Constitutional Low Arterial Tension.**—Bishop finds that some patients suffer from continuous low arterial tension without the necessary symptom of circulatory disease, an individual abnormality. Some of the patients are feeble, but others respond to the demands, and when so responding there is an improvement in the tone. This condition may give rise to alarm on the part of the physician, but when the patient can be watched from year to year, it is shown to be a physiologic state of the individual case. The special form of low tension, however, which he notices in this article is that which is the result of a constitutional condition, probably due to some inherent defect in the nervous system preventing its proper control of the blood vessels. Patients who suffer from this low arterial tension are apt to manifest other symptoms of defective nervous control. The most important form of treatment is systematic exercise. There are other conditions where iron and arsenic improve the condition when it becomes marked; still others where hot baths are indicated. Cold bathing seems to be unsatisfactory. These are in cases where the patients are not suffering from any definite disease, but realize that they are not normal and are fortunate if they fall into the hands of a practitioner who can diagnose the condition and treat it accordingly.

8 *Harelip. Daniel LaFerte.
9 *Are Women Fitted to Work Regularly? Wm. Lloyd.
10 *Pregnancy Following Double Ovariotomy. Q. W. Hunter.

8. **Harelip.**—LeFerte's article is fully illustrated, and without these illustrations the technic is not described readily. The point on which he places special stress is the making of the scar in the central line of the upper lip directly under the column of the nostrils, thus giving a more artistic result. Where one nostril is depressed, and the ala of the nose of that side spread out on the face, he dissects it from the bone and puts in a button suture, the suture penetrating from the depressed and loosened ala through to the fixed ala of the opposite side. In about five days the suture is removed, when the lip will be found to have become attached to the raw surface of the bone underneath, and the wing of the nose to have become elevated.

9. **Are Women Fitted to Work Regularly?**—The question whether women are capable of continuous mental labor under all physiologic conditions, is discussed by Lloyd, who from years of experience has come to believe that the healthy woman needs no rest at her menstrual period. Unfortunately, however, about 50 per cent. of women in civilized countries suffer more or less, and require special intervals of rest during the period of pain to avoid all possible source of trouble.

10. **Pregnancy Following Double Ovariotomy.**—Hunter reviews the reported cases of this occurrence, and questions how, in case there should be a supernumerary ovary, can the ovum gain entrance to the uterus after extirpation of both fallopian tubes. Leaving out of question the presence of a third ovary, and granting that vestiges of functionating ovarian tissue are left behind in performing a double ovariotomy, by what means and by what route can the liberated ova reach the uterine cavity if the fallopian tubes have been completely removed?

11 *The Gouty States. Thomas E. Satterthwaite.
12 *Preparation and After-treatment in Nasal Operations. H. Beaman Douglass.
13 Case of Primary Carcinoma of the Liver Which Weighed 25¾ Pounds. Increase in Body Weight. Diagnosis by Abdominal Paracentesis. Robert H. Halsey.

11 **The Gouty States**—Satterthwaite discusses the conditions and thinks the following points important. There is a general treatment of gout that should underlie every variety, whether the form be acute, subacute, chronic, aberrant, or minor, independent of manifestations that require special treatment Colchicum, in connection with the salicylates, or their congeners, or the alkaline carbonates, still holds the first place in the treatment of gout For the aberrant form there can be no specific treatment In the others, medicines play a subordinate role to diet and hygienic remedies, though the iodids are the main reliance We can make no ironclad rules with our present knowledge Each case demands a study of the individual requirements, necessities and physical limitations.

12 **Nasal Operations**—Douglass points out the advances that have been made, the value of adrenalin in connection with anesthesia, the possibility of using a much weaker solution than formerly, and the value of those now employed by European operators The best method for the production of local anesthesia is by the application of thin pledgets of cotton from which the excess of the anesthetic solution (cocain alone or with adrenalin) has been squeezed out These are placed within the nose and cover the field of operation In operating on the septum, both sides must be anesthetized The more important point is to produce a complete and sustained anesthesia The first application of cocain should be by a spray, after which the pledgets of cotton should be introduced Better results are obtained from a number of small pledgets than from one large one After the nose is thus prepared, the patient should be given a medicinal dose of whiskey or strychnin, to antidote any possible bad effects from the cocain or shock, and placed in a quiet room for 15 to 20 minutes until the cocain effect is produced thoroughly Douglass also speaks well of the Schleich method in various nasal operations, as in frontal sinus work, where it should be used for the skin, muscle and periosteum Nasal sepsis is also noticed, and its treatment, which consists of securing drainage from the nose and combating the constitutional symptoms Granulations and synechiæ are also apt to give trouble, and in slight irregularity, left after septic nasal operations, he thinks the wounds heal with fewer granulations when their surfaces look downward and when they are less disturbed His opinion is that post operative cauterization of the wound and all forms of plugging are detrimental to healing and favor the formation of granulation tissue, and that our best results are obtained by the use of antiseptic powder and non interference Hemorrhage is a very important post operative complication, and may be dangerous, especially if it is from the artery of the nasal septum Hemorrhage from the septal vein is the most frequent form If the artery is spurting from the center of the tonsil, the only treatment is to catch the bleeding point with a pair of forceps and twist it. If the hemorrhage is not arterial, and persists after fifteen or twenty minutes, the tissues should be cauterized with an electrocautery and the cut surface sewn together, according to the method which he has described In adenoid cases peroxid of hydrogen usually will control the hemorrhage In rare cases it may be necessary to use a postnasal plug Hemorrhage from the accessory sinus is rare Douglass is a thorough advocate of the use of salves and powders within the nostril after operation, and massage with a pledget of cotton on an applicator and soaked in an antiseptic solution or greased with the salve is very useful after nasal operations, if used on the cut surface after the fifth day It keeps down exuberant granulations stimulates the circulation, promotes healing and keeps the nose healthy

10 Une nouvelle modification à l'urétrotome de Maisonneuve G Bagozzi (Milan)

1 **"Prostatism" Without Enlargement of Prostate.**—Motz and Arrese have been examining postmortem 15 subjects succumbing to prostatic retention—all the symptoms indicating "prostatism," as they call it—and yet the prostates were of normal or subnormal size in all. In 5 they found evidences of chronic prostatitis, in 4 of adenoma, and in 6 of adenoid epithelioma The atony of the bladder in these cases of prostatic retention without enlargement of the prostate is not occasioned by primary atrophy of the muscles, as they were found hypertrophied in 12 out of the 15 subjects examined Nine similar cases of "prostatism" without enlargement of the prostate have been operated on by Albarran and followed to date The prostate was of normal or subnormal size, and, apparently, offered no obstacle to the emission of urine. Its extirpation, however, was followed by the re establishment of the functions of the bladder, which had been long in abeyance. The result of the surgical intervention in these cases is extremely important and instructive The findings in the bladder were identical with those found in cases of ordinary hypertrophy of the prostate, and the benefits derived from prostatectomy demonstrate that the atony of the bladder could not have been due to muscular degeneration or to arteriosclerosis of the bladder

2 **Subpubic Incision for Extraction of Foreign Bodies in Bladder.**—Legueu advocates the revival of the old "vestibular incision" for access to the bladder in women The healing afterward proceeds much more regularly and rapidly than after incision by other technic He describes a case in which he was able to extract a large foreign body—the nozzle of a syringe—from the bladder, with the minimum of traumatism and the uneventful rapid recovery of the patient He makes a curved incision between the urethra and the clitoris, the convexity toward the latter This allows access to the urethra at its emergence from the bladder, and by slitting the urethra at this point the bladder can be entered easily The sutured slit heals without any of the mishaps liable to occur when the urethra is incised from behind.

4 **Cure of Incontinence of Urine by Retro-Rectal Injection of Saline Solution**—Jaboulay explains the efficacy of this mode of treatment by assuming that the injection acts on the hypogastric plexus instead of—like the epidural injections—merely on some of the white nerves which enter into the formation of this plexus He has used injections of air or artificial serum The latter does not diffuse and escape as readily as the former, and its effect is more durable He injects 100 to 200 gm of the serum In a case cited two injections permanently cured the patient of chronic incontinence, which for years had resisted all efforts to relieve In some cases the injections have to be repeated from time to time, but as the procedure is so absolutely simple and harmless there is no objection to its repetition

7 **Segregation of Urine by Massage of Each Kidney.**—Nicolich's simple method of obtaining the urine from each kidney separately was described on page 1189

11. **Surface Communication Between Esophagus and Jejunum.**—For two years Wullstein has been studying on animals and n the cadaver various methods of establishing direct communication between certain organs with the exclusion of the intermediate ones. His aim was to unite, for instance, the esophagus with the jejunum, outside the body, the gap between being bridged by some artificial tube or by a tube formed of a barn-door flap of skin and fascia turned back on itself with the epithelium inside. Some mishap occurred in every instance which interfered with the complete success of the operation on the horizontal and hair-covered thorax of the dog. The results observed, however, amply confirmed the possibility and feasibility of such procedures, not only for this operation, but also for what he calls retropelvic colorectostomy, the union of the rectum with the descending colon, outside of the pelvis. Sauerbruch's air chamber has obviated the chief difficulties of such interventions.

12. **Early Reaction to Roentgen Treatment.**—Schmidt ascribes to an individual hypersusceptibility the erythema which develops immediately or very soon after exposure to a comparatively weak source of the Roentgen rays. It differs from the ordinary Roentgen dermatitis which develops later.

13. **Chronic Diphtheria.**—Neufeld reports a case of a diphtheritic ulcer in the pharynx, which occurred during an ordinary sore throat, but persisted for five months. There were no indications of membrane formation at any time. The diagnosis wavered long between lues and tuberculosis, until diphtheria bacilli were discovered in pure cultures. He reviews critically the literature on the subject of chronic diphtheritic and diphtheroid processes.

14. **Banti's Disease.**—Albu attempts to prove that this affection and ordinary cirrhosis of the liver form a single morbid entity, a fibrosis or fibrous degeneration of the spleen and liver, predominating in one or the other organ, according to the individual case, as the virus settles most in the spleen or in the liver. The virus affects the spleen primarily and spreads thence to the liver, the secondary lesions in the latter frequently overshadowing the primary splenic affection. To Banti belongs the credit of having first called attention to this rarer form of cirrhosis of the organs in the lower abdomen within the domain of the portal vein, but we have no reason to class it as a separate disease. The disappearance of the ascites after extirpation of the spleen in cases of Banti's disease may be permanent, but it is doubtful whether it can be regarded as an actual cure. Possibly it is due to the favorable effect of the augmented collateral circulation consecutive to the operation. If so, Albu asks, why not try extirpation of the spleen as a means of curing the ascites in cases of ordinary cirrhosis of the liver?

15. **Mode of Action of Antitoxin.**—Wassermann and Bruck agree with those who claim that the action of toxin and antitoxin in the living organism can be explained by the ordinary laws of chemical action. [Arrhenius has adopted this view, but it is disputed by Ehrlich, and the subject induced a lively discussion at the recent German Congress of Physical Chemistry, held at Bonn, May 14.—ED.]

17. **Relations Between Leucoplakia and Syphilis.**—Lublinski regards syphilis merely as a predisposing factor in the production of leucoplakia.

20. **Hyperacidity and Hypersecretion.**—Riegel insists that a sharp distinction should be made between hyperacidity and hypersecretion. The former is a qualitative excess, the latter a quantitative excess, and both may be, but are not necessarily always associated. The hypersecretion may occur only under the stimulus of food, or it may persist continuously. The latter—Reichmann's disease—is the only form of hypersecretion that has hitherto been recognized. His tests and experiences have established that in health, and even in case of dilatation of the stomach and motor incompetency, with or without hyperacidity, there is normally no spontaneous secretion of gastric juice in the fasting stomach. He has further demonstrated that the stomach in certain cases of hypersecretion is unable to expel all its acid secretions, as the small intestine will not receive it, and there is spasmodic closure of the pylorus in consequence. This enforced retention of some of the secretion, and of the ingesta, in time produces dilatation of the stomach. The motor functions of the stomach may be unimpaired, but the organ is unable to discharge its contents. On the other hand, motor insufficiency and hyperacidity do not necessarily entail hypersecretion, and the cure of the former is not inevitably followed by the disappearance of the latter, if it exists. Differentiation of alimentary hypersecretion is difficult. The symptoms resemble those of hyperacidity, but they are more constant and occur earlier, fifteen to thirty minutes after eating. The naked-eye aspect of the stomach content after a test breakfast is also characteristic, on account of the preponderance of fluid. It separates rapidly into two layers, the clear fluid above containing scraps of bread, while in case of motor insufficiency the whole forms an evenly turbid fluid; the specific gravity is higher, and the difference between the total acidity and the free HCl is comparatively large. In hypersecretion the difference between the figures is very small. He cites some instances from his clinic showing that this difference under the alizarin test was 28 in a case of motor insufficiency plus hyperacidity, and only 6 in a case of hypersecretion, the amount of stomach content being identical in each. Atropin has a quantitative influence on the secretion, but associated hyperacidity persists unmodified by it. The hypersecreting mucosa may produce a gastric juice with the same proportional acidity as previously prevailed. This explains why we are liable to encounter cases of hypersecretion without hyperacidity. He thinks that the significance of the law established by Pawlow in regard to the constant acidity of the gastric juice has not been appreciated fully as yet. It explains why the cases of "pure hyperacidity" are so refractory to therapeutic measures. Many cases diagnosed as hyperacidity and treated and cured by the most diverse measures have probably belonged to this category of alimentary hypersecretion. As our diagnostic measures gain in precision we will undoubtedly encounter such cases with greater frequency. We will further become more and more convinced that this condition is merely the incipient phase of the continuous form. Also that the latter assumes this alimentary form as the final phase during its progress toward recovery. Treatment should be addressed to the hypersecretion as the primary factor, and every effort should be made to reduce the abnormal excitability of the stomach lining. Especially in the alimentary form of hypersecretion will the temporary exclusion of the stomach from the digestive processes be found extremely beneficial. Exclusive rectal feeding often proves very useful. The diet should be regulated carefully. An albumin-fat diet not only rests, soothes and nourishes, but it reduces the amount of secretion, abolishes friction, and as the quantity of acid diminishes, the secondary spasmodic contraction of the pylorus ceases. Both atropin and oil induce more favorable conditions, but neither are directly curative. Lavage of the stomach is also useful. In the continuous form of hypersecretion it is best applied just before the last meal of the day, while in the alimentary form the stomach is given the needed rest by lavage the last thing before retiring. He never advises operative intervention on account of hypersecretion alone, as it would have no influence on the latter.
